SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

TO PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Vaccine Matter.

For the accommodation of our Subscribers, we will supply both Bovine and Humanized Vaccine Virus.

Guaranteed to be fresh and in every respect first-class.

PRICES:

Bovine Crusts,	**$1.50 each.**
Bovine Points or Quills,	**1 00 a dozen.**
Humanized Crusts,	**1.00, small.**
Humanized Crusts,	**2.00, large.**

Nothing less than half dozen sold at these prices.

The Humanized Crusts are warranted to be from typical cases, and in every instance from healthy children, with unquestionable family histories.

Please accompany the Order with the Money.

MALARIAL FEVER.*

J. R. LAMBERT, M. D., Quincy, Ill.

Malarial fever, as described to-day, is classified into intermittent, remittent and pernicious malarial fever, and malarial cachexia—all depending upon the same cause, a miasmatic poison. There is one feature common to all of these except the last, and that is fever which remits and returns periodically. The malarial poison is widely distributed over the earth's surface, both in northern countries and in the tropics, and in regions both dry and moist, but certain conditions of heat, moisture and vegetation greatly encourage its production. High annual temperature produces the more pernicious forms of malaria while more moderate temperature predisposes to the milder forms. Its effects are also seen at high elevations, as in the table lands of Castile Spain and the eastern slopes of the Andes.

The malarial poison is certainly of a very peculiar nature; a person may move into an affected locality and not be affected by the poison, then he may move to another locality known to be free from the disease, and in a period of time, from a few days to even years afterward, be brought down by its harassing symptoms. Some are affected in a very short time after exposure, others not at all. We should conclude from this that the malarial poison is not simply a gaseous emanation from decomposing vegetable matter, for no such inorganic substance is capable of producing fever of a remittent type, or of remaining latent in the system for a length of time and then breaking out all of a sudden.

The only hypothesis which would seem to explain the various manifestations of the malarial poison, is that of the existence of an infective specific organism inhabiting the soil and capable of growth when introduced into the body through the respiratory or alimentary tracts. To demonstrate this hypothesis then, we have only to prove the existence of such an organism. In 1879, Klebs and Tommasi Crudeli announced the discovery of a bacillus supposed to produce malaria. It was found in the soil taken from the Roman Campagna and grew on gelatine and other media in the form of long filaments composed of short joints. Their observations have not, however, been confirmed. In 1880 Laveran discovered a peculiar parasite in the blood of persons affected with malarial fever. His observations were little thought of till some years later, when his experiments were confirmed by Marchifavi, Celli and Golgi, in Italy, and Councilman, Osler, Sternberg, Dock, James and others in this country. The organism thus described belongs to the class Protozoa, or the lowest form of animal life. That it is a true parasitic organism is acknowledged by the highest authorities on Protozoa.

This organism, which has been called the Plasmodium Malariæ, is found in the red blood corpuscles and also in the blood in a free state. In size they vary from

* Read before Adams Co. Med. Soc., Jan. 9, 1893.

one-fourth to nearly the whole diameter of a red blood corpuscle. According to Osler they exist in the following forms: *First,* an unpigmented hyaline body within the red corpuscles which displays active movements. *Second,* a pigmented amœboid body within the red corpuscles which may increase in size and form. *Third,* a segmenting body in which the protoplasm divides into a variable number of definite small spheres. *Fourth,* crescentic bodies, the so-called crescents, which develop within the blood corpuscles and form characteristic and distinctive structures. *Fifth,* flagellate organisms which may be seen to develop from the intercellular pigment organisms, and from ovoid bodies which are altered crescents. *Sixth,* free flagella. When unstained the bodies are clear and homogeneous in appearance, very hard to detect. In a drop of fresh blood they are endowed with a amœboid movement similar to white blood corpuscles, changing their form with great activity. The pigmented amœba derive their color from the red blood corpuscles, which latter they leave in the form of yellow or colorless shells.

The plasmodium is found in all varities of malarial fever without exception. Its presence accounts in a remarkable manner for the great destruction of the red corpuscles and the deposit of pigment in all the organs of the body. According to Golgi the different paroxysms of the disease correspond to a period of segmentation in the organism; the different types of the disease being due to a predominance of a certain form of the plasmodium. The plasmodium is not capable of life and growth outside of the body on any culture media as yet experimented with, and for this reason inoculation experiments with a pure culture have not been possible. Celli and Marchiafava have successfully inoculated persons unaffected with malarial fever with blood containing the organisms, with the effect of producing the disease. The blood in these cases, which had previously been free from the plasmodii, was found to contain an abundance of the organisms. This, together with what has been said, and the fact that quinine causes the simultaneous disappearance of the plasmodium and of the malarial paroxysms, seems abundant proof that the true cause of all malarial fever is the presence of the plasmodium malariæ in the blood.

The pathological changes which occur in malarial fever are dependent in degree on the amount of poison. The most common occurrence is the pigmentation of all the organs of the body, and especially of the capillary walls of the liver and spleen. These latter organs are usually swollen, sometimes to such an extent as to cause rupture.

Accompanying these changes is the great destruction of the red blood corpuscles as before mentioned. According to Kelsch, an ague patient was found to lose one million blood discs per cubic millimetre, in twenty-four hours. When we consider that the standard number of blood discs is from five to six millions per cubic millimetre, this seems like an almost irreparable loss. General dropsy and anasarca, with effusion into the serous cavities is also a concomitant or sequel of malarial fever.

It hardly seems necessary to describe the clinical history of each type of malarial fever, for we are all familiar with the different symptoms which go to make up a paroxysm. Probably the most common form of the disease which we meet with in this locality is that in which the patient complains of pains or aching in the head, back and lower extremeties—a tired feeling. Accompanying this are usually loss of appetite, constipation, a bitter taste in the mouth on arising in the morning, a coated tongue and a foul breath, all making up a general line of symptoms to which the name bilious has been applied. The patient may complain of chills or chilliness and a feeling of pyrexia, especially towards evening. This constitutes the symptoms of probably the lightest form of malarial toxæmia.

Next in frequency is the *intermittent* type, characterized by recurring paroxysms at regular periods which consist usually of a chill, during which the thermometer shows a rise of temperature, the hot stage, and the sweating stage, following each other, and lasting variable periods of time. After the patient has been afflicted with these ten or twelve days, they may cease spontaneously without medication, but are very liable to recur; frequent recurrences leading to the condition of malarial cachexia. The most common form of intermittents is that which returns every twenty-four hours, called a quotidian. In this form the plas-

modii are small at first, gradually increasing in size, and showing very active movements. At the time of the paroxysm, they have usually grown in size sufficient to fill an entire red blood corpuscle. They then undergo segmentation or sporulation. A paroxysm occurring every forty-eight hours is called a tertian. In this the blood corpuscles contain small amœboid bodies which gradually grow and become pigmented, and about the time of the chill undergo segmentation into fifteen or twenty separate bodies, aggregating around the central clump of pigment. Very rarely we have paroxysms occurring every seventy-two hours, called quartans. Of ninty-eight cases of intermittent fever in the U. S. Army, only seventeen were quartans.

In the remittent form of malarial fever there is a constant elevation of temperature with paroxysms resembling the intermittent form. In its first stages it very much resembles typhoid fever, but can readily be diagnosed from this by a microscopical examination of the blood. The crescent-shaped amœbæ are largely responsible for this form of fever.

Pernicious malarial fever is somewhat rare in this locality. The common name for it is congestive chills. It occurs in three forms. *First*, in which the patient is seized with delirium or coma, with high fever, hot, dry skin, etc. He may regain consciousness only to be seized with another paroxysm. A third chill is usually fatal. *Second*, the algid form which usually begins with vomiting and prostration. The patient is cold with subnormal temperature. The pulse is weak, respiration rapid, and urine frequently suppressed. The whole disease tends toward adynamia and it is frequently given that name. *Third*, the hemorrhagic is another severe variety of the pernicious remittents, hæmaturia being one of the most prominent symptoms.

Malarial Cachexia, is a condition frequently seen especially in this locality. It occurs in those inhabiting our neighboring bottom lands. Those affected may have no chills at any time, but there is probably always more or less fever. They present an appearance of profound anæmia sometimes, with yellow, sallow complexions and bloodless mucous membranes. There nearly always accompany these, symptoms of gastric disorder, anorexia, pain, or heaviness in the abdominal region after eating, coated tongue, fetid breath, constipation, etc. We frequently have an association of typhoid fever symptoms with those of malaria. This has been described as typho-malarial fever and, although it hardly seems possible to me that the two etiological factors of the two diseases can unite and produce a disease in common, yet the two causes undoubtedly modify each others action and we can have typhoid fever modified by malarial, and *vice versa*. This combination is frequently seen in the Mississippi Valley and constitutes under the name of typho-malarial fever, one of the most frequent of vernal and autumnal diseases. The association of symptoms may exist in a good many forms, but probably the most common is that in which the patient is anæmic, feels generally weak and languid, with headache and a tired feeling in the lower extremities. There may or may not be pain over the abdomen, with iliac gurgling and very rarely an eruption of rose colored spots on the chest. There is evening rise of temperature, sometimes epistaxis, frequently low muttering delirium with dullness of the special senses, bowels usually constipated, anorexia and the general symptoms which we call typhoid. In fact, to my mind it is typhoid fever but it is undoubtedly modified by the malarial poison. Such cases usually respond well to quinine which strengthens my belief in their malarial origin.

In the matter of treatment we know how Sydenham, over two hundred years ago, cured intermittents with Peruvian bark. The size of the dose as given by him was, 40 grains of the powder every four hours, which represents about 1½ grains of the combined alkaloids or about one grain of quinine. It is remarkable that for two and a half centuries this drug has been used as a specific in this disease, but it is undoubtedly entitled to first rank. The form now most generally used is the sulphate of the alkaloid quinine. It has been found that one grain doses of this given three times a day, will stop nearly every paroxysm of ague, but as larger doses are much more sure to stop them, it is the common mode at present to give from 20 to 40 grains a day for the first few days and smaller doses continued for some length of time afterwards.

As to the time of administration physi-

cians differ greatly. It is my plan to give from 10 to 20 grains of quinine 4 hours before the expected paroxysm. If this can be done, the attack will nearly always be aborted. If seen right before or during the chill, this may be stopped by a teaspoonful dose of chloroform. This frequently produces quiet refreshing sleep and relief from further paroxysms. Pilocarpine, grains one-fifth hypodermically, or morphine sulphate, grains one-fourth, given right before or during the chill will also frequently stop it. During the hot stage the patient is made more comfortable by sponging the body with cool water. Following this, quinine should be given in five grain doses every four hours, till the patient shows symptoms of cinchonism. The remedy should then be reduced to wo or three grains, three times a day, nd continued for two or three weeks, and combined with iron if there be anæmia. Quinine is best given in solution with a mineral acid, preferably aromatic sulphuric acid, but the most prevalent form here is to give it in capsule. This usually answers very well, but its administration in this way should be followed by a small quantity of dilute hydrochloric acid to insure the dissolving of the gelatin coating. In the pernicious form the great indication is to cinchonize the patient as quickly as possible. This is best done by the hypodermic injection of quinine bisulphate 30 grains with 10 grains of tartaric acid, repeated every 2 or 3 hours. Or the amorphous hydrochlorate of quinine may be used in the same manner, or 40 grains of the bisulphate by enema. In the comatose form where there is such intense congestion of the brain and other internal organs, the patient should be put in a bath and douched with cold water. Nitrate of amyl or nitroglycerine are also used to reduce the internal congestion. Simpler means are hot blankets, hot water bottles, and stimulants.

It is well to remember also that pilocarpine hypodermically, or chloroform by the mouth will usually avert an approaching paroxysm. You will frequently meet with cases of malarial fever in which the patient has been taking quinine on his own prescription, in a very indiscriminate manner with little or no good resulting. These cases are usually benefited by first giving a good cathartic and following this up with twenty or thirty grains of quinine a day for three or four days, and then giving a tonic, as elixir of calisaya and iron. You will also meet with cases which hang on in spite of large doses of quinine given systematically. In these cases open the bowels freely and give one-half ounce of Warburg's tincture, undiluted, and withold all drinks. In three hours repeat the dose. The patient soon breaks out in a profuse aromatic sweat and is then usually convalescent. This is somewhat of an heroic remedy, but it is exceedingly valuable in severe forms of the disease. Next in value to quinine is arsenic, preferably in the form of Fowler's solution, five drops three times a day, and increasing until physiological effects are observed. This is a remedy of considerable value in cases of malarial fever of mild grade but long-standing. The oil of eucalyptus, one drachm a day in divided doses, and the picrate of ammonium in one-sixth grain doses, three times a day, are also recommended.

Quinine is contra-indicated in disease of the middle ear, or inflammation of the gastro-intestinal tract. It has recently been recommended to give ergotin with quinine as a preventive of tinnitus aurium. To infants, quinine is best given by enema with starch water and laudanum. To children, by disguising the taste in syrup, or aromatic elixir of licorice, or, what I prefer, syrup of yerba santa or yerbazin. The sulphates of quinidine, cinchonine and cinchonidine are all used the same as quinine, but in about one-third larger doses.

The Treatment of Pleurisy.

M. Trasbot contributes a very interesting paper (*L'Abeille Med.*) to the discussion at the French Academy of Medicine, treating the subject from the standpoint of the veterinarian. He concludes that: 1. The sero-fibrous pleurisy of animals has nothing in common with tuberculosis. 2. Frequently the relation between its development and chilling is indisputable. 3. It is impossible to liken the sero-fibrinous pleurisy of the horse to an eruptive fever, or to a cyclic disease. 4. Antiphlogistic medication and derivative applications surely exercise an advantageous action. 5. Thoracentesis can be done without danger to the horse, and constitutes a measure to which we may have recourse before the effusion gives rise to asphyxia.—*Can. Lan.*

CLINICAL LECTURES.

PARANOIA.

*HAROLD N. MOYER, M. D., and †HENRY M. LYMAN, A. M., M. D., Chicago, Ill.

Gentlemen: This patient, a boy, is 13 years old. His mother tells us that he began to act strangely in July last. He imagined that his mother was going to poison him, and that he had yellow fever and tape worms. He has one brother, who is 12 years of age and in good health. His father died of influenza at the age of 47. He was a temperate man. The mother had two aunts on her father's side who died in an insane asylum; no trouble on her mother's side.

You observe then that we have here a family history in which there is a distinct statement of mental trouble in relatives upon the mother's side, sufficiently pronounced to have placed them in an asylum. She states that domestic and financial trouble seemed to be the exciting cause of the disease on her father's side. Whatever the exciting cause the trouble seems to have skipped a generation; her own generation remaining free from any mental disturbance.

The mental trouble of the boy commenced last July, and there is no cause for it so far as the mother knows, no sickness nor injury of any kind preceding it. The patient worked for one firm nine months and for another firm four months. He has been working in a number of places since July. He would leave his places, saying that the boys kept bothering him. He is nervous, but sleeps well and his appetite is good.

That is the history of the case so far as we have elicited it. Let us analyze some of the chief points, because they are interesting in a diagnostic way. *First*, we have a family history in which there is hereditary mental trouble. *Second*, a generation back there were two cases of insanity. *Third*, the age of the boy, thirteen years, which is the period of development of puberty.

Puberty is the time of life when nervous troubles are very apt to set in, because the nutritional changes that are taking place at that period, are prone to furnish a basis for their development. There is a state of unstable equilibrium during which slight causes may push a person into disease. This is a critical period with the boy.

There was no depression in this subject, no exaltation or melancholia proper, but the disturbance began by a change in the ideas, the emotions not being affected. He conceived the delusion that his mother put something in his food to poison him and, since last July, he has constantly held to that one idea. He has told it to his brother. There is a point in the history which we have not thus far brought out. On one occasion, when the patient's mother brought home a bottle of sweet spirits of nitre, he insisted that it was some drug to put in his food, and that it was the oil of vitriol. She showed him the label on the bottle to convince him that it was not the oil of vitriol, but sweet spirits of nitre. He was not convinced of the fact and said he knew very well that the bottle was falsely labeled.

Connecting these points will give us the diagnosis of a case such as this. His delusion affects the reasoning apparatus, and is one which is logically supported by argument. This case then belongs to the class of reasoning insanities in which the logical reasoning and the judgment are primarily affected. Such cases are not accompanied by exaltation or depression, consequently we can properly class this case under the head of *paranoia*, which is a general term given to the insanities which include logical perversions or disturbances in the reasoning apparatus.

In most cases that develop in youth, or later in life, there is hereditary disease, as we find in this case. In the absence of a family history, we could assume a neurotic heredity in almost all of these cases, but when we have it distinctly stated, it aids materially in the diagnosis.

There is one form of insanity that

*Adjunct Professor of the Practice of Medicine in Rush Medical College. Neurologist to the Cook County Hospital.

†Professor of the Principles and Practice of Medicine in Rush Medical College.

might be confounded with it, and that is the so-called hebephrenia,—the insanity which developes at the period of puberty. It is called by some writers the insanity of pubescence, and has some striking peculiarities. I do not regard this case as one of hebephrenia, because in that condition faulty ideas are not so fixed and are not so thoroughly reasoned out as they are in this instance. The patient has some of the clinical appearances of hebephrenia.

Note the rather fixed attitude of the head to one side. He keeps it in that position and scarcely moves it. But the mental condition, with the mode of onset, and the logical perversion, point conclusively to *paranoia.*

Some writers do not make any distinction between paranoia developing at this age, and the insanity of pubescence. I think it is incorrect because the insanity of pubescence is a favorable form of insanity, while in a case of paranoia with distinct logical perversion, there is not the same tendency to get well. The disease remains stationary or gets worse. The patients always have certain logical defects in their mental make-up. It may be another form of mental trouble of the melancholic or exalted type. A clinical picture of hebephrenia is a variable one, whereas paranoia, developing at this time, presents constant features and has a different prognosis. These considerations lead me to say that this was a case of paranoia.

The prognosis is unfavorable. Let me again speak of a point or two in the history aside from the logical perversion and the distinctness with which he holds to the one delusion mentioned, and finds reasons for supporting it in various external circumstances and surroundings.

The history of this young man's employment is interesting. He was employed nearly two years ago for the first time, being then eleven years of age. He worked nine months in one place; the next place he worked only four months; then he ceased to have regular employment, and the present trouble developed. In every case of paranoia that has come to this clinic, we have found it distinctly stated that the patient never remained long in one place. They develop ideas and delusions regarding their surroundings and fellow workmen until they are driven from one place to another. They are rarely discharged. The employers of this boy have been satisfied with him. He has always done his work well. He has had five or six places since last July, but was not discharged from any. He left simply because he developed delusions regarding those around him.

The essential condition in paranoia is a perversion of the reasoning faculties, the emotions remaining but little, or not at all, affected.

REMARKS BY PROFESSOR LYMAN.

The case which Dr. Moyer has just presented to you is an excellent illustration of the manner in which persons develop mental disorder at the age of puberty or later in life. I remember the case of a young man who came under my observation. He was a little older than the patient before you, and his father was a man of wealth. The father came to me in the greatest distress, saying he had discovered that his son had for some time been engaged in petty thieving. There was no reason for it as the young man had a liberal allowance of money. On making an investigation, the father found his barn nearly filled with trophies which the son had brought home and deposited there. In walking along the street he would go into book stores and filch books and other things that were of little or no earthly use to him, and some of which were of no value whatever. He would take them up, put them under his coat, and store them in the barn. The only explanation for such strange behavior was mental derangement. On ordering the young man to an insane institution, and his retention there for a time, he made an excellent recovery. He came home perfectly sound in mind and body and has not manifested a symptom of the disease since.

This young man could give no reason for filching various things. His case was one of insanity of adolescence, dependent upon an unstable condition of the brain.

Dr. Moyer has called your attention to the delusions of paranoiacs; that they are fixed delusions that enter into the life of the patient and dominate all his thoughts and actions. Although active manifestations may be suppressed from time to time, still the delusion is fixed, is a part of the patient's being and he cannot get rid of it. No treatment cures it. The patient's health does not suffer; and there may be no history of sickness, disease, or ill health

of any kind; but there is usually a history of hereditary insanity in the family, among the ancestors of the patient—if not of the parents, of the grandparents, or other near relatives. The disease is very apt to skip a generation. The patient is capable of attending to his daily avocation, of conversing logically and consistently, and perhaps with vigor and interest, about everything excepting the subject of his delusion. He is perhaps able to carry on his business in a thoroughly logical, systematic way. These are characteristics of this disorder. It is not because the patient is diseased physically, it is because he was not made right in the first place. He has received from his ancestors a badly constructed brain, and this brain, like all badly constructed instruments, brings out imperfect work. It is not the kind of work that a perfect machine will produce, for the brain, when badly constituted, will be badly balanced, badly arranged and badly interpreted.

I remember a young man who came under my observation a good many years ago. The celebrated actor, Edwin Booth, was assulted here in a theatre. A man from the gallery fired a pistol at him. He was immediately arrested, taken to jail and subjected to investigation. Mr. Booth and other gentlemen appeared as witnesses. The investigation showed that the young man was eighteen or nineteen years of age, the son of a washerwoman who had a bad family history. He was impressed with the idea that he was a a great actor; that he had wonderful histrionic genius. He said that he was the son of Edwin Booth. He was asked how that could be. The lawyer said,—'Edwin Booth and your mother were not married.' He replied.—"That is true, but nevertheless Edwin Booth is my father, and I am his illegitimate son." He adhered to that view of the subject in spite of everything.—"Why did you shoot Mr. Booth if he is your father?"—"Because he wronged my mother." This was his delusion: that he was a great actor, because he was the son of an eminent actor who he believed had wronged his mother; therefore he took the law in his own hands. The young man was perfectly rational in other respects and apparently in good health. He was committed to an asylum, remained there a considerable time, and then somebody succeeded in getting him out. The first thing he did was to purchase a copy of Shakespeare, and to renew the delusive acts and thoughts that he had maintained before his confinement in the asylum. The delusion is fixed in these cases and dominates the life of the patient, and although it may be suppressed for a time, it will crop out again. When questioned in court as to why he shot Mr. Booth, he said he did not know, but he knew it was wrong, and was sorry for it. "Would you do it again?" "No." He talked as reasonably as any man who had committed a fault and was sorry for it; at the same time such patients are never trustworthy.

Another case came under my observation, a young man 22 years of age. The other members of the family thought he was insane. He had strange ideas. He had the idea that his father and mother had turned Mormons and had started a Mormon institution in their family. He was very much disturbed about Mormonism going on in the family. I asked him if he really had had these impressions, and he said—"Yes." He had gone so far as to go to the sheriff of the county and talk with him about it. I said to him—"Do you think so now?"—"No." "Are you sure that your father and mother are all right now?"—"Yes."

I then had some conversation with the father and mother and told them they must look out for the young man; that his case was a serious one; that if there was any evidence of return of his delusions, or if they found he was not manageable they should have him sent directly to an asylum and put under surveillance there. They did not like that idea. People are prejudiced against institutions of that kind, and when you talk with them about the subject many consider it an outrage upon their dignity. A short time thereafter I picked up a newspaper and saw an account of a murder committed. I learned afterwards that this young man was engaged one day in plowing in the fields, as quiet and peaceable as any young farmer, when all of a sudden he stopped his horse, left the plow, went back to the house, took his gun and shot his mother and sister and laid their bodies out on the piazza. The explanation he gave of it was this: That he became impressed with the wickedness of his family, with the Mormonism that was going on,

and while he was plowing he could not resist the impulse to go and execute divine justice upon the offenders.

So you see the delusion may be suppressed or eradicated from the mind of the patient for the time being, yet there is no certainty that it will not recur and dominate his life eventually.

COMMUNICATIONS.

CASES SHOWING THE EFFECTS OF IMPACTED CERUMEN IN THE AUDITORY CANAL.

N. W. CADY, M. D., Logansport, Ind.

In the last sixteen years it has been my lot to come across a great number of cases of body and mental discomfort which were found to result from the presence of cerumen impacted in the auditory canal, and which were promptly cured by the removal of the offending matter. The text books have little to say of this subject, yet I am satisfied from my experience that many cases of both mental and physical anguish result solely from this cause and might be readily cured if the proper steps were taken to search out the cause of the abnormal symptoms. In the sixteen years which cover the time of my practice I have observed not less than two hundred of these cases, probably a greater number. Some of them had actually been under the care of alleged aurists who somehow failed to see what was quite evident to the unaided vision of an ordinary practitioner, that the ear canal was quite filled with cerumen.

My purpose in presenting this paper is to show some of the principal symptoms that I have observed, leaving it to abler hands to point out the nervous paths through which the various reflexes make themselves manifest. The chorda tympani and its relations to the other cranial nerves may possibly explain in part some of the phenomena observed.

My first case was that of a young man of twenty-five, who desired my services on account of what he termed a "spell of biliousness." As I entered the room and he rose to meet me I noticed that he reeled and staggered as if drunk. I failed to find any evidence of indigestion or fever, but did notice that he was rather hard of hearing. A close examination of the ear, with the aid of a paper funnel showed that the ear canal was loaded with wax. The removal of this was followed by instant relief. I found little reference to this trouble in any of my text books, but it was now evident to me that here was a probable cause of trouble that might easily be overlooked.

Case two was a musician in a cowboy circus band. As the procession passed my office I saw one of the riders reel in his saddle, and immediately dismount, covering his eyes with his hands. Shortly after he appeared in my office, asking for something to relieve his dizziness. He had been getting dizzier each day, and now he said that it had reached a point where he must have relief or give up his occupation. His hearing was so badly impaired that he could not hear a watch placed against his ear. My suspicion of hardened ear-wax was soon verified, and his hearing was found to be as good as ever.

Case three was a lady who had been in the care of an alleged specialist of Washington, D. C., for two years previous. Her complaint was that she feared she was about to lose her mind. A half hour after retiring she would find herself awake and in a state of mortal terror and oppressed respiration. This would happen several times in the course of the night, and gave her good grounds for her belief. I was ten miles from my office and had only a head-mirror of my ear outfit, but a couple of hours' work with a speculum improvised from a scrap of tin, and a hook made from a hat-pin removed a most astonishing collection of ear-wax and effected a complete cure.

Cases four and five were both men of mature years, and were supposed to be

subject to some form of epilepsy. Their accounts of the mode of invasion did not correspond with that of epilepsy, and in both cases I tried the effects of a lively vermifuge to test the question as to whether tape-worm might not have something to do with the trouble, but I had only negative results. Since an intense vertigo was a prominent symptom I investigated their ears and in each case found a hard, flinty mass of wax filling the *left* ear and pressing against the ear drum. Where the plug rested the ear canal was raw and granulated. These cases came to me about two years ago and I am still waiting for a recurrence of the epileptiform attacks.

Case six was an eight year old girl, active and fond of playing boy's games. After playing furiously for a half hour she would become suddenly faint and have to lie down to avoid falling. From each ear there was extracted a cigar-shaped roll of exfoliated epidermis, and that was the end of the trouble.

Case seven was a boiler-maker, aged thirty. He was brought to me one morning at two o'clock in a state resembling melancholia with a dash of delirium tremens. His conductor told me that the night before he became so wild that four strong men could scarcely control him, and the patient himself volunteered the remark that he was losing his mind. This, by the way, is a common belief of this class of cases, and I regard it as almost pathognomonic. An hours' work with pick and syringe removed a huge quantity of wax from both ears and resulted in a complete abatement of all symptoms.

These are only a few of the cases that I have met and are selected merely as illustrating the more prominent symptoms that result from the presence of impacted cerumen in the auditory canal.

I have noticed that impacted cerumen makes itself felt most when the air is heavily loaded with moisture. The wax is hygroscopic and at such times absorbs enough water to increase its bulk and produce vertigo. I have under observation now a young man who has been suffering for four months from a gradually increasing right hemiplegia associated with intense vertigo and a mental condition very nearly resembling dementia. I found that his hearing was variable, and acting on that suggestion removed from his *left* ear a tightly impacted, extremely hard and black mass of cerumen, and from the right ear a softer mass encased in pus. Where each mass rested the ear canal was eroded and exquisitely painful. The immediate result was the disappearance of the vertigo, but it will take time to tell whether or not any other result will follow.

Occasionally I have found from one to three forgotten cotton plugs, exhaling an odor of laudanum and sweet oil, packed tightly over a mass of wax that had caused the trouble which they were intended to relieve. Buttons, beans, grains of corn and wheat, and in one case a stiff bristle, were found to be exciting causes.

The most effectual tools for the removal of these offending bodies are few and simple.

Gruber's ear specula, a two quart fountain syringe filled with a weak solution of bicarbonate of potash and fitted with a glass nozzle, a small pick with a hook $\frac{1}{32}$ inch long, and a snare about $\frac{1}{8}$ inch in diameter made of fine piano wire answer all purposes.

A tin spout to hang to the patient's ear for the purpose of conducting away the water used is convenient.

The influence which foreign bodies and impacted cerumen have in producing functional affections of the brain and nervous system is well worth investigating. Dr. Jos. Rogers, Superintendent of the Northern Asylum for the Insane at this city, has set on foot an investigation of the condition in this respect of the patients under his care, but has not as yet gone far enough to declare any results.

I am satisfied that not less than ten per cent. of the population of adult years, if examined, would show impaired hearing as a result of the presence of impacted cerumen, and that fully half of this number would suffer more or less from vertigo. As a rule there is nothing to call the patient's attention to the ear itself as the possible source of the trouble. The hearing of one ear is usually retained in part, so that the loss of function in the other ear is not noted.

Some writer has recently called attention to the fact that a great many cases of supposed "cramp" (which is the cause usually alleged in case of death by drowning) are in reality cases of aural vertigo. I have often experienced a feeling of

vertigo and most intense bewilderment from getting water in my ears when I have been swimming, and I can readily understand how the effect of an ear plug might be enhanced to a dangerous degree under the same circumstances.

CHRONIC INVERSION OF THE UTERUS.*

W. L. BRASIUS, M. D., Gallatin, Mo.

Aveling says this condition occurs once in 100,000 births. Reeves and Madden find it less frequent, and in the Vienna Lying-in-hospital we have but one inversion in 280,000 labors. When we remember that thirty per cent. of the recent cases die from shock or hemorrhage, chronic inversion of the uterus is indeed a rare condition. And yet not so rare as to be without interest to the general practitioner. If I can offer a suggestion for the succesful treatment of this condition the report of the following case will have served its purpose.

Mrs. A., aged 44; had carried an inverted uterus, with all of the attending suffering and dangers, since the birth of her only child *twenty-five years* ago; losing an incredible amount of blood at almost every menstruation, she had become a confirmed invalid. For the last five or six months much of her time was spent in bed.

On July 28th, 1892, at 11 A. M., with bladder and rectum empty, I cleansed the vagina with warm carbolized water and mopped the entire endometrium—which was very vascular—with a fifty per cent. solution of carbolic acid in glycerine and applied the sigmoid repositor devised by Dr. Aveling.

The instrument, with about two and one-half pounds pull on the rubber bands, accomplished restoration by 6 P. M. July 29th, (thirty-one hours). Ten of these hours were lost by allowing the perineal bar to rest too far backward, directing the pressure anterior to the axis of superior straight. I removed the repositor and tamponed lightly with iodoform gauze. At 7 A. M., July 31st, (thirty-six hours) uterus was found reinverted. Applied repositor, and it turned again in twelve hours. I now removed the Aveling repositor and on a similar sigmoid rod introduced the vaginal pipe of an ordinary household syringe, wound and filled with gauze for drainage. With this I gained a depth of three inches, elevating the indented funders which I maintained for ten days, with daily removal and cleansing. Then the patient menstruated, with the loss of about two ounces of blood in five days.

The cervix now closed down and she was on her feet about the house on August 16th, (nineteen days after application of repositor).

Rectum was emptied by enema and bladder with catheter during the operation. A few small doses of morphia was all the pain-reliever required.

I would suggest that the push of the repositor be in the direction of *greatest resistance*, which will usually be found in the axis of the superior straight; that the pressure be not more than will accomplish gradual reduction; that when reposition is accomplished it be maintained by elevation of the indented fundus on some kind of intra-uterine appliance similar to the one described. That the most careful antiseptic precautions be observed goes without saying.

From the limited literature at my command I have been unable to find a report of Aveling's method having been used on this side of the Atlantic. The intra-uterine appliance referred to was suggested by the demands of the case in hand.

N. B.—March 1st, 1893. Patient has menstruated regularly and with normal flow up to this time, and expresses herself as having never enjoyed better health.

*Read before the Missouri Valley Medical Society, March 16, 1893.

Good Advice.—Miss Plumleigh (choking)—Oh, Mr. Dudekin! I—I really think I've swallowed a dreadful fly! What shall I do?

Dudekin—Deah girl, better swallow some fly-papah.

IPECAC AS AN OXYTOXIC AND PARTURIFACIENT.

JNO. J. THOMAS, M. D., Youngstown, O.

Two or three years ago my attention was called to an article by Dr. Draper, a British physician, upon the use of ipecac in the first stage of labor. It was claimed that the use of this drug in small and frequent doses not only brought about relaxation and dilatation of the os, but that it actually induced vigorous contractions of the uterus; intermittent in character, differing widely from the ergotic contraction, and very closely simulating the unaided expulsatory effort of nature. Determined to put the matter to a thorough and sufficient test, I at once placed in my obstetric bag a bottle of the wine of ipecac—the preparation used by Draper—and now, having closely observed the action of the drug in some scores of cases, feel that the conclusions arrived at should be brought to the attention of the readers of the Reporter.

My conclusions are these: That ipecac induces a rapid dilatation of the os uteri; that it promotes contraction of the uterus, and that its action is fairly certain and positive in the majority of cases. The administration of ipecac is about as certain to be followed by increased vigor of contraction of the womb as is the administration of ergot. Both drugs sometimes fail, and a cause of failure which I have frequently noted is a loaded stomach; an arrest of the process of digestion and absorption; a frequent condition during labor. In my experience ipecac does not possess the power of *initiating* uterine contraction; but given a case where labor has evidently begun, and where dilatation of the os has made some progress, the pains perhaps feeble and infrequent, the use of fifteen-drop doses of wine of ipecac every fifteen minutes will usually quite speedily bring about more rapid dilatation and greatly increased force of the pains; in other words a decided shortening of the first stage. In some subjects three or four such doses will induce vomiting, when it is wise to suspend the use of the drug for a time. In many cases I have found the effect of but two doses to be so striking as to excite the remonstrance of the patient, and a refusal to take more of what led to a marked increase of her pain.

It is easy to explain how ipecac from its nauseating properties might induce softening and relaxation, thus favoring dilatation of the os, but its oxytoxic properties appear to have been overlooked by therapeutists generally. Trousseau urges its employment in post-partum hemorrhage, and Bartholow endorses the practice, but neither claim that it acts by virtue of causing uterine contraction. In retention of the lochia where the uterus was greatly relaxed, I have found ipecac to cause prompt contraction and the expulsion of contents. I have found the remedy to be helpful in retained placenta occurring in miscarriage in the fifth month. Its employment was promptly followed by contractions sufficiently strong to bring about expulsion of the secundines.

Comment upon the frequent usefulness of an agent possessing the properties claimed for ipecac, is unnecessary. Every practitioner of obstetrics has very frequently felt the need of a harmless oxytoxic, one that can be used during any stage of labor without injury to mother or child. We have this in ipecac. Ergot, of course, has an established value as a powerful excitant of uterine contraction, but its use has narrow limitations even in the second stage of labor; while in the first it is not to be thought of. And yet, I once knew a legally qualified practitioner of medicine to administer an ounce and a-half of fluid extract of ergot within twelve hours, to a woman he imagined to be in labor—the os open to about the size of a five-cent piece. The woman lived through it but the child, I believe, did not. The legally qualified practitioner is still at large—and—but as Kipling would say, "That is another story." Pardon the digression.

Ipecac is more than a nauseant or emetic. It is an oxytoxic; and a fair trial of its properties in this direction will, I am convinced, lead the practitioner making it to the formation of an estimate of its value no less high than my own.

The normal pulse-rate of Napoleon Bonaparte is said by Corvisart to have been under forty beats per minute.

IS IT CATELEPSY, DIURNAL EPILEPSY (*Petit-Mal*), HYSTERIA: CEREBRAL, SPINAL, FUNCTIONAL OR ORGANIC?

J. D. JUSTICE, M. D., Belle Plaine, Kan.

E. M. ——, a fourteen year old girl of nervous temperament, had heretofore been healthy and vigorous and enjoyed the romps and exercises usual to children raised upon a farm. Her parents are living and healthy. A married sister and one brother died of phthisis at the ages of 30 and 24, respectively.

During the summer of 1890, the child carried some large watermelons for some distance, and continued to do this daily until she began to feel dragging sensations about the sacrum and lower abdomen. From this time on, while not so active, she was apparently as healthy as ever. No attention was given to the complaint by her parents.

In June, 1891, she complained of feeling badly, and her mother, as was her custom, indulged her in some blue pills followed the next day by a dose of quinine. This latter was speedily followed by "bowel hives." The itching was so severe and protracted that both mother and child became greatly alarmed; the neighbors were brought in "for to help scratch," and finally the doctor was sent for.

Arriving some hours later I found some rise in temperature, the skin aglow, with here and there a hive welt, but otherwise the patient was resting comfortably. From that time until now she would never be pursuaded to take quinine. In a few days she was in usual health.

During the following autumn she began to have general muscular twitchings with occasional inco-ordinate movements of hand or arm, mouth or face, not unlike chorea. About this time I again saw her and, owing to choreic symptoms, put her on tonics and recommended out-door exercise and withdrawal from school.

All directions were faithfully carried out, but to no purpose. For in a few weeks she began to have paroxysms each evening. These lasted from sundown until ten o'clock and often until midnight, and during them she lost all self control. She could not sit, lie or stand and made all sorts of maniacal demonstrations. If put to bed it required strong hands to keep her from injuring herself by thrashing herself against the wall or bed. These paroxysms occurred daily for nearly a month, when all the more frantic symptoms abated. But when she was put to bed, no matter how late, the general jumping and jerking of muscles began. No remedies appeared to do the least good, but after from two to six hours she would quiet down and sleep calmly until nine or ten o'clock the next morning, when she would awake refreshed and to all outward appearances perfectly healthy. Her appetite was good; she suffered no pain; there was no paralysis nor fever, and she grew fat and developed as any girl in sound health.

During the spring of 1891, menstruation came on and while at first irregular, soon got normal. She could walk with closed eyes to an object in a known locality but could not stand steadily with eyes shut. There was no abatement of her last symptoms after the establishment of her menstrual function, but within the past six or eight months they have materially changed. This brings us to January, 1893, the date of my last examination.

For the past year her menses have been regular and of a normal character. Lungs, heart and spinal column were sound as in health; body appears symmetrical, chest full, mammary glands developed proportionately to age; she is able to sleep and eat well, but after sunset each day she could not walk unless supported by a chair or the walls of the room.

I entered the family sitting room precisely at 5 P. M. on the day of my last visit and was greeted by the girl and her mother. The girl walked about the room in a perfectly normal way, but when requested to close her eyes and walk to a known object she could not do it—could not take two steps forward without falling. When requested to stand with her eyes shut, she would fall like a chunk of wood; but she could go about the room as before when her eyes were open.

A rest was now taken and our conversation turned to other topics. At sunset I asked her to walk. She replied "I cannot; the spell is on." I asked her how she

knew, and she stated that a dull ache always occurred in the front part of the head and forehead. If outdoors at play unmindful of the time, she felt this head symptom, she would run to the house, and, if too far away, she would fall to her knees and complete the distance by crawling. I asked her to try and she managed to get to her feet and walk sideways along the room supported by the wall. I endeavored in every way to get her to walk properly, but could not.

Muscular co-ordination is completely at fault. Neither can she walk if personally supported, as she says holding to a person or allowing them to hold her causes her to lose her balance on account of dizziness. While allowed to sit she can use her hands as well as ever. She plays games, knits, reads, sews or converses and no one would suspect her condition.

There has never been anything like a convulsion or paralysis. Her tongue is clear, and no tender spots can be found.

A number of physicians have seen and proposed to cure her, but she continues to resist remedies and to remain a puzzle, at least to me.

SOCIETY REPORTS.

SURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting February 13th, 1893.

Dr. J. M. Mathews, President *pro tem*, in the Chair.

STRANGULATED FEMORAL HERNIA; RESECTION OF THE GUT AT THE END OF ELEVEN DAYS; END TO END ANASTOMOSIS; WOLFLER'S METHOD MODIFIED; RECOVERY.

[Abstract.]

Dr. Ap. Morgan Vance: I was called January 30th, 1893, by the attending physician to see K. G., aged 33; domestic; giving the history that eleven days previously she was taken sick suddenly with vomiting, followed by purging; purging ceased early first day, vomiting continued until seen by the writer. Evidently thorough examination had not been made by the attending physician on account of the extreme modesty of the patient. Closer investigation revealed strangulated femoral hernia of the left side. The patient gave evidence of extreme exhaustion, pulse being 150, the temperature, according to the physician in attendance, sub-normal. No previous history of hernia could be obtained and the patient had never been seriously ill before, having occasionally suffered from "bilious attacks" of short duration.

Nitro-glycerine, one one-hundredth grain, was administered hypodermically at once, and patient removed to the Norton Infirmary where, after slight preparation, operation for the relief of her condition was begun.

The tumor was found to be about the size of a hen's egg; sac contained half ounce of very dark fluid; sac was much thicker than is ordinarily found in a recent hernia, so it is probable that the hernia had existed without the patient's knowledge. The very tight constriction was relieved by the hernia knife, and after thorough irrigation with sterilized filtered water, the intestine was carefully drawn out, when one large perforation discharging fecal matter was brought into view. The intestine was sphacelous in the line of constriction which included a large portion of the convexity, the mesenteric border not being involved. This line of slough was fully four inches in length. Resection was immediately determined upon, and an end to end anastomosis decided to be best suited to the condition. Eight inches of intestine were quickly removed with scissors; instead of clamps being used, the assistants making digital compression on either side of the strangulated portion.

There was no hemorrhage and the suturing was rapidly done with cat-gut number 0. During the whole procedure the parts were frequently douched, and

every care taken to prevent infection of the cavity. With some little difficulty the sutured part was returned to the abdomen, the sac being removed high up, and deep approximation sutures applied to the canal. The wound was closed with silkworm gut, with a gauze drain in the lower angle. The patient's condition at this time was better than when first seen, the pulse being 135 when the operation was commenced, falling to 120 before its completion. The operation was begun two hours after patient was first seen; there was certainly a very decided effect from the nitro-glycerine; the operation occupied fifty-three minutes.

The fact that the patient had continued so long without nourishment rendered her chances of recovery much less, as an element of exhaustion had to be considered and combatted. Vomiting continued several hours after operation, the substance being a greenish watery fluid. Hypodermics of morphia were given as needed for several days. Twenty-four hours after operation patient received and retained two drams of wine and appolinaris water; afternoon of the same day she was given wine and beef peptonoids. Morning of the third day she was given an enemata of water, one pint, which was returned slightly colored. Later, same day, an enemata of epsom salts, glycerine and water was given, a medium sized, partly formed movement resulting. She passed considerable gas and complained of griping pains in the abdomen. The wound was dressed February 6th, and stitches removed. A slight discharge of serum at the lower angle of the wound was noted which continued through the day. Patient's general condition at this time was excellent; continued to improve until the tenth day when she had four large thin stools which were controlled by paregoric and bismuth sub-nitrate.

In every case of emergency of this kind a rapid decision is necessary as to what is best, and this depends entirely upon the condition of the patient. To my mind only one of the two procedures is legitimate. If the patient is *in extremis* and plainly unable to withstand a prolonged operation the production of an artificial anus is the operation; but if, in the estimation of the operator, the condition justifies it, even to straining a point, the patient should have the benefit of the doubt and complete operation be performed as in this case.

Either terminal or lateral anastomosis by absorbable rings or plates is decidedly less feasible or surgical as a cœlotomy is made necessary from inability to return the repaired intestine through the small hernial opening. The risk in cœlotomy is in septisizing the cavity, which is rendered *nil* by working entirely through a slightly enlarged hernial opening.

DISCUSSION.

Dr. W. O. Roberts: Dr. Vance is to be congratulated upon the thoroughness with which the operation was done and the result obtained. I agree with him in what he says with reference to the management of these cases, viz: That where the case has gone so far as to lead us to believe the patient will not be able to stand a prolonged operative procedure, an artificial anus is the thing to do. That would be very easily accomplished and could be done very quickly under the circumstances. But where the condition warrants the procedure I believe the operation of resection certainly preferable. I have only done this operation once—resection in strangulated hernia—and that was in quite an old man at the city hospital. Dr. Rodman assisted in the operation. Patient did well for four days and I thought we were going to get a good result, but on the fifth day after the operation, the patient suddenly grew worse and died quickly. Post mortem revealed the fact that the line of union had given away and allowed the extravasation of fecal matter into the peritoneal cavity. Cases of strangulated hernia after gangrene has occurred, are usually in such condition that very little is to be accomplished by operative interference; the condition of the patient is such that they seldom rally. I thought I was going to have a case something similar to this yesterday. I was called to operate on a case of strangulated hernia that had been treated for colic for three or four days before the true nature of the trouble was discovered, but I was informed upon my arrival at the house that the patient and his friends had decided not to have any operative interference.

Bearing upon this question we ought to impress upon the general practitioner the great importance of earlier interference in

strangulated hernia. In some cases of this trouble, termed by Erichsen "active strangulation," gangrene takes place very quickly, only a few hours being required, whereas in what he terms "passive form of strangulation" it may be several days before the protruded portion becomes gangrenous. I saw a case not a great while ago, where a man had been treated for colic and strangulated hernia was not suspected until he was almost in collapse, still, under operative interference, he came out all right.

Dr. Vance did not state the condition of his patient's tongue after the operation.

Dr. A. M. Vance: The condition of the tongue was very good, with red furrows and red edge.

Dr. W. O. Roberts: It was probably some septic condition from the absorption of the products of putrifaction before Dr. Vance saw the patient, that caused the symptoms following the operation.

Dr. H. H. Grant: I think there are a good many reasons why Dr. Vance should congratulate himself that he used the method of operation employed, especially because he has a very satisfactory result. I notice in the last number of the *Annals of Surgery* the report of a successful case by an Italian surgeon, in which almost exactly the same operation was done under almost the same conditions. Femoral hernia in a woman fifty-four years of age, with end to end suture of the gut after resection of the gangrenous portion. I think in the progress of surgery at the present day, surgeons have become bolder, and have more or less overcome some of the prejudices which existed a few years ago with regard to the advisability of making an artificial anus after conditions of this kind, rather than do a complete operation. It seems to me if there is ever a time, however, in which it is advisable to make an artificial anus rather than do a resection, it would be in a femoral hernia after gangrene had taken place.

It is undoubtedly a very difficult thing to make this character of a resection, because, it not only takes a great deal of time to get the intestine prepared by this method, but the danger of sloughing of the gut is great, owing to the number of sutures interfering with the circulation; further, the proper approximation of the intestines is not always easily accomplished, and the probability of the suture giving way and consequent fecal fistula or extravasation of fecal matter into the cavity, is more likely after a condition of this kind than it would be if the operation were done by some of the other methods of anastomosis or resection. Besides when a gangrenous condition of the intestine is present, the general depression of the patient is very great.

For these reasons it seems to me to be the best time to make an artificial anus; or at least the time at which it would be less appropriate to subject the patient to the greater risk and the long operation necessary in the establishment of continuity of the bowel. Of course it would be practically impossible to accomplish intestinal anastomosis in a condition of this kind, without completing extension of the wound and opening the abdominal cavity if the sutured gut could not be returned, and under these conditions it would not be permissible, practically.

Where it is intended to complete the operation by intestinal anastomosis, either by the method of plates or by direct sutures as is more frequently practiced, I should certainly prefer it to the circular suturing as advised by Dr. Vance. I have been able to complete the operation of intestinal anastomosis without plates, in experiments upon animals, in eight minutes and am satisfied it can be done in less time by use of the clamp, a method which I have recently suggested. Using the method of direct suture Abbe claims the operation can be done in less than thirty minutes, and with competent assistance and special surgical skill perhaps this can be done. I should not favor the operation done by Dr. Vance under the circumstances unless there were strong evidences that the patient would likely rally; as under other conditions I do not think we should subject the patient to the complete operation, but should resort to the artificial anus. It seems to me that there is no legimate criticism that can be made of these cases, because a surgeon at the bedside is the best judge as to what should be done, and each case is a rule of itself. In the case operated upon by Dr. Vance, it is probable the majority of us would have decided as he did and given the patient the benefit of the doubt.

Dr. E. R. Palmer: This case recalls to

my mind one detailed by Prof. Bayless several years ago; a case of strangulated femoral hernia in a young woman who was so exceeding modest that she would not allow an examination. I notice Dr. Vance states that the extreme condition of his patient was due to the fact of her extreme modesty. In the case to which I refer, of course the patient died, and Prof. Bayless in reporting it, presented as a pathological specimen the external genitals removed post mortem with the hymen intact proving the unquestionable virginity of the woman, with the statement that he did so simply in justification of the fact of his non-interference in the case.

Dr. W. L. Rodman: I too wish to add my congratulations to Dr. Vance for his good work in this case. I do not believe there is such a thing as luck in intestinal work. I think he has stated the proposition very correctly and fairly—we are driven to one of two things in cases of this kind. I believe, however, in the majority of instances where the hernia has been strangulated for so long a time, and especially hernia of the femoral variety where the constriction is greater than in ingunial hernia, the condition of the patient will be such as to exclude resection. Such cases should have an artificial anus established. The operation of enterectomy is a very old one, recently given much attention by Ransohoff and others. It has never had a certain footing in surgery. The principal thing in the operation is which method of suture is best; and that seems to be the battle ground over which surgeons have fought more than any other. The majority of operators I think prefer the ordinary Lembert or the Czerny modification; the result in Dr. Vance's case proves the suture he used is as good as any other. Senn, who has done so much intestinal work, uses a suture something after the fashion of Jouberts, where after a section of gut has been removed the proximal is telescoped into the distal end.

Another feature of Dr. Vance's operation was having his two assistants grasp the two ends of the gut between their fingers, instead of using the ordinary clamp of Making. Over this clamp is rubber tubing to prevent injury to intestinal coats. I believe the clamp better than trusting the proximal and distal ends of the gut to two assistants, as by its use there will be less danger of extravasation of fecal matter into the peritoneal cavity. They also enable one to operate without trained assistants—sometimes a necessity.

Dr. W. C. Dugan: I think the suture Dr. Vance used can be applied more rapidly than any other. The way Dr. Vance has been using the suture is the way it is generally used by operators, simply passing it through the entire thickness of the gut rather than only down to the mucosa. I cannot help agreeing with Dr. Vance that it is simpler than the Lembert or the Lembert-Czerny, and its application requiring less time which is very important in such work.

In regard to the length of time, I think that certainly more than half the time consumed in Dr. Vance's operation (fifty-three minutes) was in cleansing. It seems to me that the operation as described by Dr. Vance, not counting the time necessary for preparation and cleansing, can be done in fifteen minutes. I did the operation, about one year ago in the city hospital, for gangrene following intestinal strangulation, in thirty-two minutes. But the patient was in profound collapse and died without reacting.

I notice Dr. Vance used the hernia knife for opening the sac. I think in these cases it is better and safer to cut down upon the strangulation from without, rather than with the hernia knife underneath.

Concerning the question of an artificial anus or resection in cases of this character, this is a matter that must be decided at the operating table and not by theory. A few years ago most operators would have condemned this operation and favored the artificial anus, but of late there is a strong disposition to go to the other extreme and restore the continuity at one sitting.

Dr. A. M. Vance: I have very little to say in closing. I believe the suture employed by me is the most secure for this form of anastomosis. I have had considerable experience with this modification of Wolfler's method in experiments upon animals; have resected intestine of the same dog twice, the last time fed the dog large quantities of meat and bread immediately after the operation; still there was evidently perfect union of the gut as the dog recovered promptly. In examining the gut for evidence of constriction, where

resection was done I found simply a mere line, perfect union having taken place with no decrease of the lumen.

Fifty-three minutes for this operation was quite a long time, but as Dr. Dugan says, it was from the time I commenced shaving the pudendum until the operation was completed—until the last external suture was applied. I do not think the actual intestinal work occupied more than twenty to twenty-five minutes. I have resected the intestine in a similar case where the constriction had existed eight days, the herina having been handled very roughly by a charlatan previous to my seeing the patient. In this case I am convinced that the operation of resection was a perfect success; however, the woman died a few days after the operation of sepsis from another cause.

As Dr. Grant has stated, I think the surgeon at the operating table is the best judge as to what should be done in these cases, and no definite rule can be formulated as to whether the mode of procedure should be resection or an artificial anus. I do not consider lateral anastomosis advisable in any case of this nature.

CONTINUED REPORT.

Dr. W. C. Dugan: About seven months ago I reported to this society a case of sarcoma of the kidney, exhibiting the specimen removed. One of the members at the time asked my opinion as to whether the child would live three months. I simply want to state that the patient is still living and there is no evidence of a return of the trouble.

INGUINAL HERNIA AND EPIDIDYMITIS IN A CHILD AGED SEVEN YEARS.

Dr. W. L. Rodman: I saw a case about two weeks ago that is unique so far as my experience goes. I was called about ten o'clock at night, to operate upon a case of strangulated hernia. I found the attending physician at the bedside of a little patient about seven years of age, with the history that he had had a left inguinal hernia for two years. Examining the patient I found the left half of the scrotum red and seemingly a little swollen. I made the diagnosis (although I have never seen a case before in a child under fifteen years of age) of epididymitis instead of strangulated hernia. Upon further examination I found a perfectly reducible inguinal hernia. The inflammation was allowed to subside, when I did a radical operation for cure of the hernia, because the patient was unable to wear a truss; he had tried three or four kinds of trusses none of which would retain the hernia. Then I thought there possibly was also a piece of omentum in the hernia which was irreducible; this turned out to be the case at the operation.

The reason I report the case is to bring forth discussion of epididymitis in a child so young as this. I believe it was due to irritation of the truss which was not well applied. I did Kocher's operation for radical cure and the case has progressed satisfactorily in every respect.

DISCUSSION.

Dr. H. H. Grant: I think it was probably a case of traumatic epididymitis.

Dr. A. M. Vance I have seen several times this condition in children, which I attributed to mal-application of the truss. The truss is sometimes applied over the scrotum rather than over the canal, producing bruising and irritation of the parts, and inflammation results.

Dr. W. O. Roberts: I saw this case with Dr. Rodman. It was a well-marked case of epididymitis, and I do not think there is any doubt but the pressure from the truss caused it. I know of nothing else which could have produced it, unless it be mumps. By the way, has any member ever seen an attack of mumps begin in the testicle primarily and effect the parotid gland secondarily?

I have seen two cases of epididymitis caused by mumps, where the parotid swelling was so slight as to be hardly noticeable. Strange to say in both cases the epididymitis was on the right side, same side as the mumps.

OPHTHALMIA NEONATORUM AND HYDROCELE; CHILD AGED 10 DAYS.

Dr. Wm. Cheatham: I saw a child some time ago with ophthalmia neonatorum, and the mother called my attention to the swollen condition of the scrotum. The child was only ten days old.

Dr. E. R. Palmer: I sent my assistant to see the child referred to by Dr. Cheatham, and he found a pro-

nounced hydrocele. The child suffered with severe ophthalmia neonatorum with a hydrocele, which was evidently due to mechanical causes connected with parturition. My advice was to let the scrotum alone. I do not see why mechanical causes should not produce epididymitis.

Concerning the metastasis of mumps, the man has not yet been born, and the scientist has not yet been found that can explain what that is. I have under observation now a medical student who had mumps as a boy; he had double mumps and double orchitis. He consulted me and wanted to know whether he would ever be able to propagate. He had two testicles each about the size of an ordinary almond. I gave him the same direction that I usually give in these cases, which, by the way, is a very simple one when you want to determine a man's virility; that is, to put a condom half on and have connection and bring the semen to me for examination. He followed my direction and we made a careful microscopical examination of the specimen of semen. In the whole mass of semen we found only one irregularly-shaped spermatazoon. I told the man that he had lost his virility and was absolutely unable to impregnate.

When a man has mumps on the right side it is very natural that the disease should develop in the testicle on the same side. As for mumps beginning in the testicle I have never heard of such a suggestion. I cannot conceive of anything more destructive of virility than mumps.

Dr. W. C. Dugan: I noticed some time ago in the *Medical News Gazette* where several articles, discussing the metastasis of mumps, maintained that there was no metastasis at all; that the testicle was one of the glands of the body, consequently was liable to partake of this trouble the same as the parotid gland, and that the inflammation of the parotid gland is but slightly modified by the complicating epididymitis. So since both glands are involved at the same time metastasis does not occur; that cases on record showed in the course of an epidemic of mumps there would be a certain per cent. of involvment of the testicle without any swelling of the parotid at all. Most writers on the subject report cases which prove beyond doubt the correctness of these clinical facts.

The case reported by Dr. Rodman calls to mind one that I saw about eighteen months ago with Drs. Cartledge and Douglas. There was great swelling of the right side of the scrotum, the skin was very red and it looked as though the testicle was acutely inflamed and about to suppurate, although the patient had all the symptoms of strangulated hernia. We cluded to introduce the aspirator needle to determine if it was the testicle, and it was found to be a strangulated direct inguinal hernia, having evidently existed only a few hours and yet the gut was found to be gangrenous. Operation was performed and the man died a few days afterward.

PERIOSTIAL SARCOMA OF THE JAW.

Dr. H. H. Grant: I have a case to report that I operated upon at the Children's Hospital two weeks ago, for what I looked upon as periostial sarcoma of the upper jaw, beginning in the alveolar process just underneath the nose, in a child ten years old. A year before, this tumor was about the size of an almond; I removed it with the assistance of Dr. Rodman, and in about eight months it returned. After examining it again, I recommended operation. The family desired that Dr. Vance should see it; he did so and agreed with me, and thought we perhaps could do as much by dissecting the tumor out, scraping the alveolar process with a curette and cauterizing it with a thermo-cautery, as we could in any other way. The situation of the growth was such as to involve both superior maxillary bones, both allæ were involved as high up as the vomer and nasal bones. After discussing the matter we decided that an incision could be made each side of the growth, the tumor carefully dissected out, and the bone scraped, which would at least result in temporary relief. It was clear that no other operation could be done that would promise any relief, without complete resection of the alveolar process of the superior maxillary bone, or at least beyond the articulation of the bones of the nose with the superior maxillary, badly disfiguring the face and mouth. In presenting the matter to the parents I told them that I thought it would be wiser to scrape away the growth as thoroughly as we could, rather than do

an operation which would certainly deform the child for life and, in the event that the growth returned, its complete removal then by the more severe operation would not be rendered any more difficult. After considering the matter they consented to having any operation done that we thought advisable. The conservative operation was done with the assistance of Dr. Vance, and the growth thoroughly scraped away. There was considerable hemorrhage which delayed the work very materially. It was finally completed and dressed, and the child has done very well since. Examination proves the trouble to be sarcoma of the round cell variety.

DISCUSSION.

DR A. M. VANCE: I agreed with Dr. Grant in this procedure. It seemed to me that the more severe operation, taking away almost the entire front of the face, resulting in much greater disfiguration without, in my opinion, any better chances of complete extirpation of the growth, was hardly advisable in this case and I believe that the operation as performed will result in relief which will be as permanent as by any other operation. It is probable that the growth will return, but it was removed with a great deal of thoroughness and in my opinion the conservative operation was the proper one in this case.

DR. W. O. ROBERTS: As I understood Dr. Grant, there was no involvement of the bone proper, consequently I do not see any necessity for removing a section of it. I think the doctor did everything that possibly could be done.

DR. W. C. DUGAN: If this growth was from the maxillary bone, it was very unusual, especially its location. I presume that it sprang from the intermediate or inter-maxillary portion, and that the maxillary proper was not involved. If such was its location I hardly think it advisable to remove the entire jaw as was thought by Dr. Grant.

DR. W. L. RODMAN: I saw this patient as Dr. Grant says, when he did the first operation, which I think was more than a year ago. The primary operation was very thoroughly done as is shown by the fact that the growth did not recur at once. I have a lingering suspicion that when a complete microscopical examination of this growth is made, it will not prove to be a pure round cell sarcoma. The round cell variety is the most malignant of all sarcomata, and I am strongly inclined to the opinion, from the apparent slowness of its development and from its situation, occurring either from the under surface of the periosteum or probably from the bone itself, that the growth will prove to have not only small round cells, but will have probably a good many giant and spindle cells. The history of the case indicates this form of sarcoma rather than the round cell variety.

DR. H. H. GRANT: With reference to the suggestion made by Dr. Roberts and referred to by Dr. Dugan: This growth was at least one and one-half inches over the alveolar process of the superior maxillary bone, and evidently sprang from it. Its point of origin and its evident growth was from the superior maxillary alveolar process, one and one-half inches in breadth—three-fourths of an inch each way from the central portion—and the removal of any portion of the superior maxillary bone less than three-fourths of an inch from the central portion would not have taken away the cancerous growth.

With respect to the characteristics mentioned by Dr. Rodman, it occurs to me that perhaps he is a little misled in the matter. While this operation was not performed until a year after the removal of the first growth, still the cancer recurred in five or six months after the first operation, and was considerably larger than when he assisted in its removal. Sarcomata that are not traumatic are usually much slower in their growth. Diagnosis of round cell sarcoma was made by the microscopist, still perhaps it is not very definitely settled.

SARCOMA OF THE JAW—IODOFORM POISONING.

DR. W. C. DUGAN: The morning after the last meeting of this society, I saw a patient from Glasgow, Ky., with a tumor of five weeks standing, on the left side of the jaw. There was some bulging on the face which gave him trouble; he had been treated by the family dentist with poultices, etc., for some time before a physician was called in. The doctor who saw the patient before being brought to this city, made diagnosis of sarcoma of the jaw. He was taken to St. Joseph's Infirmary

where I saw him the next morning after arrival, and confirmed the diagnosis made by his physician, advising removal of the growth at once. The tumor was of considerable size and seemed to be very virulent, consequently I recommended early operation. On the third day after being sent to the Infirmary operation was performed. The median incision was made and the flap turned back from the median line; the jaw was then sawn through and the orbit of the superior maxillary bone lifted out, and it was found that the tumor extended backwards involving the entire fossa. The first step in the operation was tracheotomy. I believe this should be the primary step in all operations of this character; it is very simple and not a very bloody operation.

A peculiar feature is that this patient had a typical case of iodoform poisoning; rapid pulse, high temperature, delirium, jerking, etc.,—one of the most marked cases of iodoform poisoning that I ever saw. The iodoform tampon was removed and the symptoms gradually subsided. He was up about the room on the fourth day after operation, having no pain at all. At the end of the second week he returned to his home feeling well, and we hoped by the operation he had secured a further lease on life. He had been home about four or five days when his physician wrote me that he did not like the way he was getting along; that it was returning along the line of the incision. I wrote him to have the patient come back to Louisville at once, and upon examination I found the tumor was as large as the end of your finger, evidently the same growth but there was none in the line of the incision in the soft palate. Dr. Cheatham saw the case and examined his nose. The growth rapidly extended to the soft and hard palate and all thought of further operative interference was abandoned. His physician is now using Pyoctonin both locally and injected, and I shall report the result.

Upon examination it proved to be small round cell sarcoma.

DISCUSSION.

Dr. A. M. Vance: I have heard of very few successful operations for malignant growth on the upper jaw. I agree with Dr. Grant in the case of alveolar sarcoma, it is almost impossible to prevent serious disfiguration when the growth involves the upper jaw, provided a complete operation is done. I have refused several times to operate on such cases; they would go away and be operated upon by others, finally returning to be treated until they died, in a few weeks or a few months. In the history of the lower jaw it is entirely different, there we can get rid of it and the patient is liable to go along for some time; but I have never known removal of a malignant growth of the upper jaw to do any good for any great length of time.

Dr. H. H. Grant: It occurs to me that the report Dr. Dugan gave of the operative steps in his case is as nearly the ideal method as could be described. I have seen the operation done very much as he suggested, with the exception that the chisel was used in the median line. I am disposed to favor conservatism in these cases, but of course whenever the sarcomatous growth has extended far enough to involve the soft parts of the bone, as in the antrum or in fact any of the medullary canals within the bone, then the likelihood of anything like a conservative operation in the immediate vicinity is almost out of the question, and as it is impossible to cut wide of such growths in the face it is oftener best to do nothing.

SQUAMOUS ECZEMA.

Dr. E. R. Palmer: I have had immediately subsequent to this very cold weather, four cases of face eruption in women of doubtful virtue that have been diagnosticated by doctors as syphilitic eruption—diagnosis probably based largely upon the fact that the women were of questionable virtue and therefore liable to this trouble. They came to me with considerable alarm and a great deal of anxiety and stated frankly to me that their doctor had said they had syphilis. They were all of the better class of such women and in each there was history of syphilis, they each had an eczema of the squamous variety, I believe superinduced by the cold weather and the soap they had been using. In two or three of the cases the back, arms and hands were involved. None of the cases were attended with enlargement of the lymphatic glands, nor anything that would point toward syphilis, yet in all four cases diagnosis had been positively made of syphilis. It simply goes to show

the tendency on the part of doctors to take any eruption on women of questionable virture to be syphilitic. I think we should be exceedingly careful in making diagnosis of syphilis based simply upon an eruption.

DISCUSSION.

Dr. A. M Vance: Do you not think that some of this eruption was due to cosmetics, etc. ?

Dr. E. R. Palmer: It may be, I had not thought of that. One of the patients came back to me with the eruption still on the back of her hands, saying she had gotten all right again until she disregarded my injunctions and bathed a great deal trying to keep clean, then the eruption came back. When this case first came to me the eruption on her face looked very much like pityriasis versicolor. We know that this affection does not affect the face, so of course it was out of the question.

THE WESTERN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Annual Meeting: Kansas City, Missouri, December, 27th, 1892.

[OFFICIAL REPORT.]

Dr. T. J. Shreves, Des Moines, Ia., read a paper on "Prolapsus Vaginal."

DISCUSSION.

Dr. Todd: The paper of Dr. Shreves is very suggestive and deserves more consideration than time will permit of.

Relaxation or prolapsus of the vaginal wall may be due to a variety of circumstances. It may result from an injury to the perineum—an injury to the deeper perineal structures or to the orifice of the vagina—in which the posterior vaginal wall is weakened and the uterus fails to receive that support that the vaginal wall gives it and, hence, is very liable to undergo some form of displacement.

All relaxations of the vagina are not of traumatic origin by any means, although the perineum may be torn. It is possible that injury to some other part has taken place during parturition; and we very well know that any injury to the vaginal wall or perineum, or to any of the parts concerned in the process of parturition, interferes very materially with the process of labor. An injury of this kind although of slight character—a tear, somewhere we will say, in the vaginal wall—results in the impeding of involution. That is to say, a physiological condition cannot go *pari passu* with a pathological condition. The pathological condition prevents the physiological changes which are to follow. So it happens that with almost any kind of injury during parturition we have an arrest of involution, or a preventing of the involution of the vagina and of the uterus. Then again, we have a certain class of individuals in which there is the strongest tendency to conditions of this sort. They are of flabby muscle; there is a flaccid state of the entire organism. It is, perhaps, an inheritance for, as they say, it runs in families whose members are particularly prone to affections of the mucous membranes. They may not have tuberculosis of the lungs, but they are liable to have bronchial discharges, and catarrhal conditions of the stomach and bowel, of the urinary tract and of the vagina and uterus. They have leucorrhœa without any known cause; the mother had it and the grandmother had it. It is a constitutional condition. In these cases, where the condition is congenital, that relaxed condition of the vagina can be produced by leucorrhœa—as these cases are very apt to be attended by leucorrhœa, and are not apt to be attended by uterine displacements. They are not *apt* to be—hardly ever, if at all, in primipara, but occasionally happening in multipara. If a woman has borne many children she is very apt to have a relaxed state of the vaginal walls. Ordinarily she does not have any uterine displacement unless there has been a laceration. Those who make many examinations will find every degree of relaxed vaginal walls—every degree of tonicity. In some the muscular fibers are always in a state of tension; on the other hand, in

this class of cases I am speaking of, they are in a constant state of relaxation.

Now treatment for the latter sort of trouble isn't to be done by mechanical means. It is true that the vagina can be so relaxed as to cause cystocele or rectocele with prolapsus of the vaginal wall or prolapsus of the bladder, where one might have occasion to use a mechanical support to keep the uterus up and the vaginal wall on a stretch, because the uterus is very likely to descend in such cases. But in that class the vice is constitutional and the remedy is to give tone to the entire individual, by the use of ergot, arsenious acid or some form of strychnia or nux vomica, or like drugs.

If I remember correctly, in Dr. Shreves' case there was an existing pregnancy of about two and a half months, and that this relaxed condition of the vagina pre-existed. That, of course, favored some displacement of the uterus because the relaxed vaginal wall allows the uterus to fall back. Dr. Shreves was very fortunate in being able to come out as well as he did. It doesn't always happen so. I remember a case that happened some little time ago, in the hands of one of our prominent physicians who called me in consultation. The lady was advanced in gestation about two and a half months if I recollect right. She was the wife of one of our ministers here. A romping brother suddenly threw himself into her lap and the uterus was forced backwards by the violence done by the child. The doctor was called in and attempted reduction by the ordinary methods but failed. Twenty-one hours had elapsed and in the meantime retroversion had taken place. Although chloroform was given, an effort made to replace the uterus was without result. Placing her in the knee-chest position, continued efforts were made until the woman had become so fatigued that we were compelled to abandon the endeavor for the night—it was then late in the evening. The next morning we again attempted to restore the uterus to its place by all the methods known; we used pressure upon the organ but it was utterly immovable. The uterus had not been displaced more than thirty-six or forty-eight hours. Well, the woman became fatigued and there was considerable tenderness, so I proposed to the doctor in attendance that we introduce a sound into the uterine cavity, which we did and the woman aborted. Within ten or twelve hours afterwards the uterus had begun to restore itself, and when I returned again, the woman was all right.

But in Dr. Shreves' case, the great relaxation and the great flaccidity of the wall allowed the organ to be replaced just as easily as it got out of place. It went out of place without any violence and was restored without any violence or difficulty.

I hardly need say that the paper of Dr. Shreves, while it is suggestive, covers only a small portion of the complications that we are apt to find in such cases—not those present, but those which may follow. The time comes, in all cases where the vaginal wall is relaxed, that something must be done else prolapsus or some other displacement of the uterus will take place.

If the individual be one of that class I referred to, we should aim to give tone to the general system as well as use local treatment. I am in the habit of resorting to a local support for the vaginal wall until the parts have been restored to their normal condition. One valuable means of overcoming this relaxed condition of the vaginal wall, which so much favors uterine displacements, is found in the application on wool of the fluid extract of ergot in glycerine, used as a pessary. Glycerine has a wonderful power in bringing about compression and tonicity of the parts. Those who use this application will soon discover how difficult, after a few applications, it is to introduce the finger into the vagina. If it is kept up for a considerable time, I have no doubt that permanent tonicity of the parts will be gained.

Dr. Price: Injuries in parturition predisposing to the complications under consideration, are very instructive.

A gentleman has dropped me a note asking whether I use anæsthetics in obstetrics. If you will permit me a word about this, I will answer simply "very rarely." My reasons are as follows: The use of anæsthetics in obstetrics favors a world of mischief on the part of the obstetrician. Go to half-a-dozen cases of women in active labor, three of them multiparæ and three of them primiparæ, and none of you are prepared to say that any of them will be terminated in an hour or three hours or six hours. I have

before now, after examining a woman carefully, felt that I could go off and do one or two sections and come back in time; but after examining her during pain and waiting a few moments, I discover that it will, in all probability, be over in half an hour. At other times I have gone off and done one or two sections, and come back in good time.

As to the use of anæsthetics in private obstetrical cases, many interesting stories are told about the use of forceps. One gentleman, saluting another with his bag, —"Forceps case?"—"Yes; reed bird for supper." When you give your anæsthetic you are about to make up your mind to terminate that labor. Now take a primipara and give her an anæsthetic; wait an hour and a half; you prolong your anæsthesia and apply your forceps without knowing to what extent the os is dilated or dilatable, and you split the cervix and perineum that has neither softened nor dilated and pull a head with a least diameter of four inches, over the pelvic floor. That has a direct bearing on the subject under discussion. You burst asunder the ischio-perineal fascias or muscles, or more, in advance of that child's head and predispose the woman to a capacious and relaxed outlet, with cystocele and recto-vaginocele following in most of cases. So I unhesitatingly condemn the indiscriminate, injurious and foolish use of anæsthetics. I know perfectly well from large experience in gynecology and repairing of injuries to the soft parts incident to parturition, that anæsthetics have been at the bottom of much of the post-partum trouble.

Another cause is the early and foolish use of ergot. In mining districts among women attended largely by midwives, the labor begins with ergot, is followed by ergot and finished with ergot, and you will find most mutilations among women in mining districts. Wherever you find midwives controlling midwifery, you will find most frightful mutilations. I have found—and I have given the matter no small amount of study and consideration—for instance in consultation, the doctor will tell me she has been in labor since five o'clock yesterday: and after examining a woman, I tell him to go home, see twelve patients and come back. But he wants to terminate the labor. The patient is walking the floor and pacing from side to side. The cervix is fairly well dilated, the descent isn't very well marked notwithstanding it is a primipara. I tell him: "Go home and get something to eat, *get your buggy* and drive your practice for three hours and then stop in." That is the last I hear of him. Now I could easily terminate that labor with the forceps, but I should look upon it as a criminal assault, crippling that woman for life. There isn't a single indication—the membranes are intact, the cervix is not dilated, the parts are soft and moist, she is bearing it very well, there is no constitutional disturbance whatever and it is simply a matter of time. Physicians or obstetricians must learn to wait; they must cultivate that happy grace—patience.

Now, sir, with regard to prolapsus or relaxation—it is a very bad term; it does not mean much—the doctor's paper is interesting and instructive, and I agree with him wholly except so far as the injuries of the pelvic floor are concerned—and I don't know that I differ with him there—in predisposing to these protrusions or prolapses of the soft parts, the anterior and posterior vaginal walls. He has beautifully called our attention to the class of cases that are strongly predisposed. We find some young women of relaxed fibre—unmarried women, never having borne a child—with the cervix protruding at the vulva, and we have no solution for the condition except that it is an hereditary tendency and predisposition. Nor have we very much in the way of treatment for the relief of such a patient.

But in those cases of cysto-, and recto-vaginocele, following retroversion and retroflexion, resulting from injuries incident to parturition, very exceptionally do we find a protrusion of this character without finding the ischio-perineal fascias—the pelvic floor or diaphragm, if you please—broken down. In short, if you plant your finger in the right or the left sulcus, you will find nothing resisting in the recto-vaginal region, not even a levator ani. If you plant your finger in the right sulcus and pull it down you may feel some fibres of the right levator ani resisting your finger, but on the left side you will rarely find anything. If you will introduce your finger into the bowel and press out through the vulva you will find that you have nothing but the rectal and

vaginal mucous membranes. The ischio-perineal facias and muscles are all gone. Everything had been crowded up in advance of a child's head and ruptured *post-vaginam*. On the left side you will generally find the injuries the most marked.

The signs of the condition are notable: The patient will sit down and cross her legs or she will stand with her legs crossed, and if you ask her why she does it, she will tell you that it gives her comfort—gives her a sense of support. She loses that sensation of everything coming down and out or protruding from her, by crossing her limbs. If you make compression laterally, posterior to the vulva and anterior to the anus, and push up the perineum, and ask if that gives relief she will say—yes. Again, if you ask if she has a sense of defecating through the vagina when constipated she will say—yes. The resistance of the walls of the vagina is even less than that of the sphincter, the rectocele rolls out before the sphincter yields and thus produces sensations of defecation through the vagina.

Now place fingers in the right and the left sulcus and pass them under the rami of the ischii—and all these cases are about alike except those congenital cases and those of virgins alluded to—and trace the evolution. It sums up a loss of support. Notwithstanding we have had many discussions and much written about the support being from above and about the schio-utero-sacral ligaments and broad ligaments and all that sort of thing, I am not willing to admit that the supports are not largely from below. Take a whole school of vigorous, healthy spinsters who are taking an active interest in domestic duties and social life, and none of them have a descent or prolapsus. But some of them get married, the pelvic floor is broken down and they have a prolapsus. Surely that condition of affairs follows some injury to the pelvic floor that did not antedate marriage. Emmet discusses fully these injuries to the pelvic floor and also discusses the utero-sacral ligaments and the broad ligaments. The broad ligaments are simply reflexions of the peritoneum, and I don't think much of the broad ligaments as I find them, for the support of the uterus.

The doctor called attention to defective involution. Unless the cycle of reproduction is complete, some mischief lurks. The parturition should be normal and the lactation as well must be normal. At present, there is a tendency to bottle every baby, and I sometimes wonder why the good Lord does not send a barrel of soothing syrup and a bottle with the baby. In all such cases there must be defective involution. There is a relaxed pelvic floor and there is a large and heavy uterus; it descends, goes into the hollow of the sacrum and becomes retroposed and retroverted or retroflexed. With this descensus a deflection follows and there is an obstruction to the return of the veinous blood. The uterus becomes engorged and heavier, and this increases the descensus until it becomes a procidentia.

Now if you will redress that uterus, place it at a high circulation level and unload it of its blood, you will, in twenty-four or thirty-six hours, find that you will have a very much smaller and lighter organ. That is just what comes of the knee-chest position and the cotton and glycerine dressing dwelt upon. We have at our command that treatment, that redressing, for a large and retroflexed or retroverted uterus with descensus. Then follow that with whatever you like; but so far as my own work is concerned, I would insist on restoring the supports by one of Emmet's beautiful methods of plastic work—the perineal operation in injuries to the pelvic floor.

You can bring up the pelvic floor and make a woman about as physically virginal as it is possible to make her. And I know from a long experience and the use of every conceivable effort to repair those injuires, that there is nothing in plastic surgery that compares with the methods of Emmet in all these lesions. I simply look upon him as the "father" of plastic work.

One theory in regard to the discomfort that is curious and interesting, belongs to an Indianapolis man, and is that the peculiar discomfort suffered in locomotion or standing is due to a loss of co-ordination. For instance if you will make a woman contract her sphincter, if you will watch the action of the pelvic muscles in nausea and vomiting under ether, you will see there is a condition of asymmetry in the contraction of those muscles. Her discomfort is due largely to a loss of co-ordination in her pelvic floor and pelvic muscles, something like that loss of co-ordination

of the fore-arm in an injury to the flexors or extensors. This Indianapolis man has given a very pleasing solution. I have forgotton his name.

Dr. Shreves: To my mind there was no other alternative than to make a diagnosis of laceration of the superior portion of the vaginal tract from the cervix, from the fact that I found presenting a tumor, soft, yielding, flabby, protruding beyond the vulva at least two inches; that on introducing the index finger I found complete retroversion, with the fundus resting on the rectum and the cervix pointing against the pubis making at least four inches between the point of the cervix and the lower portion of this presenting tumor; and that in the center of this presenting tumor was as perfect an external os as ever I discovered through a speculum. I had no means satisfactory to my mind, of making any other diagnosis than that the superior portion of the vaginal tract had been torn loose from the cervix and simply inverted—turned inside out—carrying the external os with it. As a matter of fact we understand that the point of the cervix is covered with a mucous membrane, and that mucous membrane is reflected up on the side of the cervix and then back again and, passing downward, is inserted into the vaginal walls. Well, my philosophy was that this was torn loose, that the vulva was simply turned inside out, the external os presenting two inches beyond the vulva, and on further examinations I saw no reason to change my diagnosis.

It was the first case of the kind that I ever had any experience with, and I have not been able to find that a like case has been reported. Consequently I brought a report of the case to this society, feeling anxious that the members present should discuss it very fully and convince me, if possible, that I was in error in diagnosis. I am satisfied that all men are liable to fail at times; but in this case I didn't understand how it was possible to make a mistake in diagnosis when there was at least four inches intervening between the external os and the point of the cervix. The case has fully recovered.

When I put back the displaced uterus the second time, I passed my finger around the point of the cervix, forcing the vaginal tube up so as to pass over the neck, and retained it in that position by tamponing the vagina with wool. As a matter of course, when all that followed took place, a retroversion occurred, and when I replaced it the second time I had to go through the procedure precisely as I did in the first instance and retain the vagina pressed up firmly on the point of the cer-vix.

A Shrewd Servant.

An exchange prints the following: An incident which happened a few days ago in this city shows the servant girls are about as sharp as the average run of people. Mrs. —— is a married woman who is evidently unable to keep a servant girl more than six weeks. She is overbearing and tyrannical, and makes it intensely hot for the domestic. A few days ago, so the neighbors say, her servant came in and said, as her month was up, she would take her money and go. "My gracious, Maggie, you must stay a few weeks longer. You know that I expect to be sick soon. I will give you ten dollars more a month." "I can't stay ma'am. I have engaged another place." So the hard-hearted Maggie packed her trunk, and an hour later, as she was leaving, she said: "If you please ma'am, I hope the boy will be a fine one." "Why are you so positive about it being a boy?" "Wy sure ma'am, no girl would stay with you *nine months*."

After six months of widowhood, Bridget consented again to enter the married state. A few weeks after she was led to the altar, her former mistress met her on the street, dressed in deepest mourning.

"Why, Bridget!" she exclaimed, "for whom are you in black?"

"For poor Tim, me furrst husband, mum. When he died I was that poor I could'nt, but I said if ever I could I would, and me new man, Mike, is as ginerous as a Lord."

"Do you believe in the transmigration of souls?"

"Not I. And you?"

"I am convinced of it."

"Indeed! Then what were you once upon a time?"

"An ass."

"When?"

"When I lent you that sovereign!"

CORRESPONDENCE.

NEW YORK LETTER.*

In a recent clinical lecture, while discussing the question of prognosis in chronic valvular disease of the heart, Dr. A. A. Smith, Professor of Practice in the Bellevue Hospital Medical College, made some statements in regard to the effects of the tobacco habit in heart disease, which varied considerably from the teachings of most authors on this point. While admitting the evil of the use of tobacco to a certain extent, he said that it was not always wise to make a patient with any chronic disease, particularly cardiac disease, stop the tobacco habit. The effects on the nervous system of a sudden change from a habit that has been long continued is often more deleterious to the patient than would be the continuance of the habit. There are many cases of heart disease met with in private practice, in patients who are habitual smokers, in which it is noticed that palpitation, dyspnœa, and præcordial distress are excited upon the slightest exertion when the use of tobacco has been shut off, while during the continuance of the habit compensation was well kept and the patient experienced no particularly ill effects from his valvular lesion.

Dr. Smith referred to a young physician whom he knew ten years ago, who had grave valvular lesions and in whose case the prognosis as to time was but a few years; the young man thought that he would take all the comfort he could while he lived, so began a rather immoderate use of tobacco; he is living yet and his prospects are more brilliant than they were ten years ago. Another case was mentioned of a cigar-maker who was told that he must cease the use of tobacco, as he had a double valvular lesion; the man stopped the habit altogether for two weeks, during which time he suffered so from dyspnœa and palpitation that he began the habit again with a relief of these symptoms. Dr. Smith said that he now has under observation two Russian ladies who contracted the cigarette habit in their native country; both have organic heart disease; as long as they continue the cigarette habit they experience no severe results from their heart disease but, as soon as they attempt to break away from the habit symptoms of loss of compensation and of beginning predominant dilatation are observed. The professor did not wish to convey the idea that the cases mentioned above were typical ones, or that the use of tobacco was justifiable in all cases of heart disease, or even in the majority of them, but simply wished to show that tobacco was not contra-indicated in all cases, as well as that a bad prognosis is not to be made in a patient with valvular lesions on the ground that he is addicted to the use of tobacco.

* * *

A couple of cases of septic infection following the very slight operation of removing corns were recently reported at a meeting at the Academy of Medicine. One of the patients was a young man who had pared his own corns, using a common knife, and of course paying no heed to aseptic precautions. In a few days fever and symptoms of septic infection set in, with great pain and swelling in one of the shoulder joints. The patient was a rheumatic and the symptoms were thought to be of a rheumatic nature; salycilates were given and anti-rheumatic treatment carried out, but failed to relieve the symptoms. The swelling in the shoulder continued to increase; an incision was made and a large amount of pus evacuated. The patient was seriously ill for two months.

The other patient was an elderly lady who had several corns removed by a chiropodist. In a few days fever, muscular pains, and marked nervous prostration set in. A swelling soon developed at the sight of a contused wound on the arm; this swelling was opened and a large amount of thin, dark-colored pus turned out; pus had extravasated between the muscular planes and in the subcutaneous cellular tissue of the arm; the patient gradually grew weaker and in ten days died.

*Special Correspondent to THE MEDICAL AND SURGICAL REPORTER.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MARCH 25TH, 1893.

EDITORIAL.

PRACTICAL CLEANLINESS.

Abdominal surgery has about settled the question as to the necessity of chemical solutions, or so-called germicides, in practical surgery. Some eminent general surgeons, who still corrode their hands with bichloride and like reagents, admit it is done mostly to satisfy Mrs. Grundy. The abdominal surgeons who are now achieving the best results use nothing but boiled clean water in their work. This greatly simplifies matters.

Theories are worthless when contradicted by every day experience. We may marvel much over the wonderful array of bugs and bug-ptomaines turned loose upon the surgeon and his patient by the tireless German microscopist; but, so long as the application of hot water alone gives such good results as it does, we need not consider the desirability of cornering the market in any of the many bug-poisons foisted upon us by the germ theory.

It is a great relief to the accomplished and experienced surgeon as well as to the learner just on the threshold of the art, to be able to cut loose from the slavery of *antiseptics* and to adhere only to the gospel of cleanliness.

Of course, one can go too far in the protest against a system deemed false and cumbersome. When Lawson Tait held his silkworm gut sutures in his mouth while making a perineorraphy merely to show the Germans his contempt for their germ theory and its attendant germicides, he violated a canon of *asepsis* as well as of *antisepsis* and laid himself open to just criticism.

A system often becomes top-heavy and falls by its own weight. The industry with which the biologist is constantly adding species to the number of pus-producing and infecting micro-organisms all ready studied, begins to set one thinking that, when these little enemies of mankind exist in such countless myriads of an infinite number of species all ready to pounce upon the helpless and injured, creation is a failure. Pope's well known verse should read "A bugless man's the noblest work of God."

In fact the endless invention and multi-

plication of pathogenic microbes becomes practically a strong *reductio ad absurdum* argument for their harmfulness.

It is laid down as a rule in our text books that pus can exist only in the presence of moisture, heat and bacteria. But a fourth factor is equally necessary; that is, necrotic or devitalized tissue. Hence bacteria are looked upon by some scientists as mere scavengers of the system, helping to get rid of material destroyed by some process either chemical or traumatic. That they become harmful only when their products become so abundant as to furnish new pabulum for their own sustenance, by overwhelming vital processes in tissues rendered less resistant by causes foreign to germs of any kind.

A rule of conduct or a method may be essentially correct although founded on, or originating in, a false theory. This is conceded of the routine of antiseptics. Instead of destroying matter inimical to life it has merely washed it away by the fluid holding the germicides in solution.

Thus out of the chaos of Antiseptics has gradually evolved the simplicity of Asepsis. The idea now obtains of removing the infinitesimal sources of sepsis with soap and water instead of poisoning them and the patient alike with chemicals.

TRANSLATIONS.

DEATH IN INFANTS FROM HYPERTROPHY OF THE THYMUS.†

Mussy (*La Mèd. Moderne*, January 21, 1893) says that simple hypertrophy of the thymus is rare. Most of the cases of inflammation of that organ are due to hyperemia or to hemorrhage of the size of a pin's head, disseminated through the organ and originating from injury during labor. True inflammation is denied by most of the authors. Friedleben observed it once in a young man eighteen years of age in whom the thymus gland persisted becoming of an enormous size filling the mediastinum, adhering to the pericardium and causing death by suffocation. Syphilis may be a cause of increase in size. Dubois in 1850, noted four observations of purulent thymus in syphilitic children. This opinion, accepted by Depaul, Henoch, Viederhofen, was opposed by Virchow, who claimed that during fetal life this organ contained a milky juice entirely analogous to pus. Other authors, Depaul, Bednar, have cited cases in which they have noted cysts containing fluid, yellow, and of the dimension of a bean, which they have regarded as softened gummata. However it may be, syphilitic lesions are rare, since Furth in 200 autopsies found them only seven times, and Parrot even denies their existence completely.

Primary tuberculosis of the thymus has never been demonstrated; secondary tuberculosis although rare, has been recognized several times following invasion of the ganglia of the mediastinum. As to malignant tumors, experience is far from proving the assertion of Birsch-Hirschfeld, who, in 1877, claimed that tumors of the mediastinum, in the form of soft lymphosarcomata, had for their point of origin the thymus gland. Friedleben does not cite any case, and since his work, but two or three well authenticated cases have been recorded in medical literature.

As to whether hypertrophy of the thymus, the causes of which are still surrounded by obscurity, is the origin of the attacks of suffocation known under the name of spasm of the glottis or thymic asthma and which may occasion death, is a much disputed question. In the eighteenth century the thymus had been charged with producing asthma in infants. But it was Kopp who first in 1830, embodied this doctrine. This opinion was quickly attacked in Germany and Italy by numerous writers: Pagenstecher, Wunderlich, Hecker, to cite only the most important.

†Translated for THE MEDICAL AND SURGICAL REPORTER by W. A. N. Dorland, M. D.

In 1855, Hirsch advanced anew this hypothesis, opposed strongly by Fingerhutt, Canstatt, Marsh, who took sides with the view of the nervous origin. In France, the question was but little agitated. Blache, Valleix, Trousseau, all inclining rather towards eclampsia, quickly withdrew when the thesis of Herard appeared in 1847. This eminent physician concluded his observations thus: "The thymus is an organ whose volume and weight are very variable in children in good health—this is dependent upon the constitution of the child. In the so-called thymic asthma the variations of the volume correspond to variations in the constitution, and have nothing to do with the production of the attacks of suffocation." Rilliet and Barthey also defended the convulsive origin. More recently Weit has returned to the view of thymic asthma, and he has been followed by a certain number of physicians, in Germany especially; Schœle of Dantzig, Soltmann of Breslau, Pott of Halle, Fleischmann, Recklingausen, Jacobi of New York, etc.

Jacobi, in 150 cases of glottic spasm, noted ten deaths; Soltmann in 425 cases (in ten years), forty-eight deaths; Pott, in 176 cases, fifteen deaths; on an average ten to twelve to the hundred. In these fatal cases about the third of the infants succumbed suddenly. It may be seen therefore, that the prognosis of this affection is far from being good, and it becomes important to avert the possible fatal issue.

Pott, in his memoir published in 1892, gave the results of the autopsies which he had made upon eight children who had died suddenly in an attack of suffocation. The thymus weighed on an average 30 grammes; in one case 40 grammes; that is three times the normal weight. The dimensions were as follows: Length, seven centimeters; breadth, four centimeters; thickness, two centimeters. Moreover, adhesions existed to the pericardium, near to its reflexion on to the large vessels of the neck. Beyond doubt, in this case, there was a marked hypertrophy of the thymus gland; on the other hand the absence of any lesion in the other organs prevented the ascribing to such cause the death of the child.

In all of these cases, here is, from a clinical point of view, how the patient most usually acts: On placing a spoon in the mouth of the child to examine the throat, it suddenly throws the head back, respires violently, the eyes roll upward, and the pupils are extremely dilated. The lips are cyanosed and swollen as is the rest of the visage. The tongue is pressed against the jaws, bloated, cyanotic and touching the palate. The veins of the neck turgid, the fists are closed, containing the thumb strongly flexed, the forearm is contracted and pronated. The lower extremities are extended, the toes flexed, and the verbetral column slightly curved. Some fibrillary motions in the muscles of the face may be noted, some inspiratory movements that do not suffice to cause the air to enter into the respiratory passages. Then, suddenly, the contracture disappears, the visage pales, the tongue and the lips become livid, and in one or two minutes the infant becomes a corpse. Towards the end of the attack the urine and feces escape, the murmurs of the heart are scarcely audible and the pulse scarcely sensible, and the corneal and pharyngeal reflexes are abolished.

Artificial respiration, tracheotomy, electrization of the recurrent nerves have never succeeded in reëstablishing the vital functions. How does the hypertrophied thymus act in the production of this fatal accident? Is this organ capable of flattening the trachea and so deforming it as to prevent the entrance of any air into it? It is very difficult to adopt an opinion that may stand the test. Scheele has demonstrated experimentally that a weight of 1000 grammes is necessary to produce a complete flattening of an infant's trachea. Here is a more probable hypothesis than that death is due to pressure of the large organ upon the trachea. The distance that separates the sternal fourchette from the vertebral column in an infant is on an average two centimeters, and there is also the thickness that an hypertrophied thymus may attain. In this closed space the enlarged gland forms adhesions with the pericardium, the large vessels and the trachea. Coming in contact with the latter, the two organs unite, and a fatty degeneration of the artificial wall takes place. Little by little the trachea softens, then suddenly, under the influence of a sharp flexion of the head, the trachea is flattened, completely obliterated and the asphyxia commences with

the nervous phenomena already cited.

The thymic tumor may also compress the recurrent nerves, as any other tumor of the mediastinum, and occasion a glottic spasm; it may also give its weight and adhesions to the heart and the large vessels; exercise by compression upon the ventricle or upon the pulmonary artery a sort of cardiac paralysis of which mention has been made in describing the crisis.

The thymus gland, therefore, acts as do tubercular glands in the child by compressing the trachea little by little, finishing by occluding it, by compressing the recurrent nerves, the heart, the great vessels, and becomes for these two reasons (an obstacle to the entrance of air and the circulation of the blood) the point of departure of excitation of the centers and nervous phenomena which are dependent upon them. To conclude, as Sanné has said, there exists, in addition to the eclamptic form of spasm of the glottis, a compression form due to hypertrophy of the thymus, and we may add that in the latter form more especially does sudden death follow the attack of suffocation.

Bi-Lateral Oophorectomy for the Cure of Osteomalacia.*

E. Kummer reports the following case: Patient, aged 39, had given birth to seven children without instrumental aid; the last birth was three years ago. The beginning of the disease was eight years previous, first appearing with pains in the extremities. Since 1886 increasing deformity in the lower extremities. Four months ago irregular and profuse menstruation. Pelvic measurement between the spines 18¾ cm., the crista 26, the trochanter 24.5, the diagonal conjugate 7.

Oöphorectomy performed February 9, 1891. Recovery with entire disappearance of former pains and complete arrest of the disease. So far thirty-eight cases have been operated for osteomalacia, with but one death and a complete arrest of the disease in all. In regard to the history of this disease, the author coincides with Fehling in that he believes that the nervous system of the genital organs influences the disease of the bones.—(*Revue de Med., de la Luisse*, Rom. xii. 7-92.)

* Translated for The Medical and Surgical Reporter, by Marie B. Werner, M. D.

The Treatment of Retention of Cysts of the Tubes by Dilatation of the Uterus.*

A. Zabolotsky reports in an inaugural dissertation, (Petersburg, 1892), observations upon twenty-six patients on whom the diagnosis was made of the retention cysts, in the Clinic of Prof. Slarveansky, of Petersburg, who were treated by dilatation of the uterus. The means for dilatation were laminaria, tupulo or sponge tents, tampons of villiet and the bougies of Hagar.

Zabolotsky believes that laminaria tents produce the best results for dilatation. That the dilatation of the uterus is usually followed by emptying of the retention cysts. In only four out of the twenty-six cases he noticed an increase of temperature. The usual time for this treatment is thirteen days, and the shortest is six days; the patient is compelled to remain in bed throughout the time. Of the twenty-six, ten had cysts on both sides; seventeen were thoroughly cured; three had a return, were treated in the same manner and were discharged well. In five the contraction of the cysts could be felt and the patients considered themselves better. Sixteen of these patients still come to the clinic.—*Schmidt's Jahrb.* Bd. 237, No 1.

The Destiny of a Ligature Used in Ovariotomy after 5½ Years.*

N. Komarewski reports under this head that a patient in whom ovariotomy had been performed 5½ years before and who died during a recent confinement, a microscopical examination of the stump showed the complete absorption or disappearance of the silk ligature.—*Chir. Annalen.*, 1892. Bd. ii., p. 333.

Invisible Color.—Professor—Microscopical investigations lead us to believe that there are colors too delicate to be discerned by the human eye, invisible colors, we may call them.

Student—I know the name of one of them, sir.

Professor (surprised)—Indeed! What is it?

Student—Blind man's buff.—*Texas Sift.*

*Translated for The Medical and Surgical Reporter, by Marie B. Werner, M. D.

BACTERIOLOGICAL NOTES.

The Distribution of the Bacilli of Diphtheria in the Human Body.

The opinion has been generally entertained heretofore, that the bacilli of diphtheria were localized in the false membrane characteristic of the disease.

Frosch (*Zeit. f. Hygiene* xiii, 1893, pp. 49) gives the results of his investigation of fifteen fatal cases of diphtheria. In five of these the specific bacteria were not found in the internal organs, in the other ten the diphtheria bacilli were isolated from the blood and various organs. The bacteriological examinations were made as soon as possible after the death of the patient. The ordinary method of making agar plates was employed. In some of the cases the bacilli were unusually distributed through the body, as indicated by their isolation from the blood, spleen, liver, kidneys, cervical and bronchial lymphatic glands, lung (when hepatized) pericardial and pleuritic effusion, and the brain. In a few cases they appeared in the cultures from spleen or kidneys only. Babes, Kolisko and Paltauf, and Spronck are the only observers who have made similar observations in the past. The results obtained by Frosch bring out with clearness a very important fact in the pathology of diphtheria.

The Preparation of Haffkine's Anti-Cholera Vaccines.

According to Haffkine's method protection against cholera is brought about by acclimatising the system first to a weak virus and afterwards to a strong cholera poison. The materials used in bringing about such a condition in the animal body, and the method of preparing the same are described by Wright in a recent (Feb. 4, 1893) number of the *British Med. Journal.* The vaccines consist of emulsions of attenuated and of exalted cholera cultures. They may be of two kinds. An emulsion (1), of the living cholera bacilli (living vaccines) or, (2), of cholera bacilli that have been killed by the action of dilute carbolic acid (carbolized vaccines). The living vaccines possess a greater vaccinating power, but the carbolized vaccines have the advantage in being perfectly safe to handle or to leave about. They do not appear to be impaired by keeping, and could be sent out from some central place where they could be made in quantity.

The attenuated cultures are obtained by M. Haffkine by cultivating the cholera bacillus in media which are continually aerated at a temperature of 39° C. When the cholera bacilli have been grown under these unfavorable conditions for some time, they become so weakened that they cause a local œdema instead of necrosis when they are injected into the subcutaneous tissue of a guinea-pig. The attenuated germs can be cultivated indefinitely in agar tubes without regaining any of their lost virulence. The "exhalted" vaccines are obtained by growing the cholera bacilli in the peritoneal cavities of a series of guinea-pigs As each guinea-pig dies the fluid which is found in the peritoneal cavity is inoculated into a second pig and so on until the virus has passed through a series of twenty or thirty animals. During such a long series it is very difficult to avoid contamination of the virus unless the strictest care is exercised. The cholera bacilli are not sufficiently virulent when isolated from the intestinal discharge of cholera patients.

The emulsions are prepared from the attenuated and "exhalted" cholera bacteria, by mixing the surface growth on agar cultures one day old, with sterilized bouillon, two or three ccm. of liquid for each agar culture. The carbolized vaccines are prepared in precisely the same manner as the others but instead of bouillon, a five per cent. solution of carbolic acid is used. In these vaccines there are no living cholera germs. The vaccines are injected beneath the skin with a sterilized hypodermic syringe. The injection of the "exalted" vaccine is made about five days after the injection of the attenuated virus.

A Case of Glanders in Man.

The fact that glanders are communicable from horse to man has long been known, but the record of an authentic case in which the specific bacteria were demonstrated in both subjects of the di-

sease, is not of common occurrence. Clement (*The Journal of Comparative Medicine and Veterinary Archives,* February, 1893) gives a full account of a case of glanders in a man in Baltimore, with the post-mortem notes on both the horse and the man. The clinical history given is as follows: "Mr. H., white, age 34 years, was employed as a nurse in a car stable, and also took care of a horse belonging to his brother. He had a habit of biting his finger-nails until the skin would bleed. One day he noticed a swelling on the end of his little finger, which grew rapidly worse and became very painful. An abscess soon formed in the axilla. This was followed by the appearance of sores on other parts of the body, swelling of the nares, hyperæsthesia, and semi-unconsciousness. The attending physician thought that he had a case of septicæmia to deal with, but in consultation the diagnosis of glanders was made. The patient was unable to give an intelligent history of his case and it was not known by the physician that he had attended a horse which presented symptoms of glanders."

After the death of Mr. H. an investigation was made by the State Veterinarian and the health authorities, which revealed the fact that the horse belonging to the deceased's brother showed symptoms of glanders. It was immediately put in quarantine. A few days later it was treated with mallein obtained from the Department of Agriculture. The reaction was decided and the animal was killed and found to have glanders.

Mallein is being prepared under the direction of Dr. Welch, from cultures obtained from a guinea pig that died from the inoculation of infected tissues from the man.

The Differentiation of the Bacillus Coli Communis and the Bacillus Typho Abdominalis.

Luksch (*Centralblatt f. Bacteriologie u. Parasitenkund* xii, 1892, p. 47) gives the results of his study of these bacteria. In their cultural characters the same conclusions have been known for some time, but in their morphology he points out a difference not heretofore considered in differentiating these bacteria. The motility of bacteria is due to the presence of minute hair-like appendages called flagella. On the bacillus of typhoid fever Luksch found as many as from eight to twelve of these delicate filaments, while on the bacilli coli communis he could not find more than three flagella and usually a less number. He also found that the flagella could be stained much more readily on the typhoid germs than on the coli bacteria. The motility of the typhoid bacilli was much more marked, as determined by the examination of fresh preparations, than that of the coli germs. The flagella were stained by the use of Löeffer's method, which consists in treating cover-glass preparation with a mordant before applying the staining fluid.

To Obtain and Mount Crystals of Haemoglobin.

Here is a simple and excellent plan that we have used for many years: Let fall a minute drop of blood on the center of a perfectly clean slip, and let it stand until under a loupe you can see it beginning to dry at the edges. Take a little thick chloroform solution of balsam, or a benzol solution of dammar, and first spin a little ring around the blood, winding up by letting a good sized drop fall directly on the blood so as to completely cover the latter and unite with the ring already spun around it. Now put your slide under a bell glass, and allow it to stand until the balsam is quite hard and dry on top. In summer this will take forty-eight hours; in winter longer, unless the surrounding air is kept warm artificially. When the balsam is dry dip a clean spatula in benzol and pass it rapidly through it, removing the surplus, heat your cover-glass and drop it while hot on the slip, and finish your mount in the usual way. On examining your slide you will find that beautiful crystals of hæmoglobin have formed in the center, and the other elements of the blood have been permanently preserved.—*Nat. Druggist.*

DOCTOR—Troubled with sleeplessness, eh? Eat something before going to bed.

PATIENT—Why, doctor, you once told me never to eat anything before going to bed.

DOCTOR (with dignity)—That, madam, was 1889. Science has made great strides since then.

ABSTRACTS.

ON SOME OF THE TROPHO-NEUROSES ASSOCIATED WITH ABNORMALITY OF THE THYROID GLAND.

Dr. Solomon Solis-Cohen reported (Phila. Co. Med. Soc., Feb. 8, 1893,) and exhibited photographs of two cases of akromegalia, in both of which there was apparent absence of the thyroid gland, and marked skeletal changes in addition to those in the face, hands, and spine. The patients where males, one twenty-five years of age, the other fifty-one years old. In neither case was there any eye-lesion. The case of the younger man had been previously reported to the College of Physicians. In the elder man headache, drowsiness, forgetfulness, thickness and scanning of speech, and excessive polyuria were present. The symptoms had been partially relieved by picrotoxin, the headache especially. This drug was a vasomotor regulator and useful in many of the conditions to be discussed. It was necessary to say "apparent absence" of the thyroid gland, because only *post-mortem* could absence or atrophy be unqualifiedly affirmed. Embryologically the pituitary body and thyroid gland were intimately related, and it appeared not improbable that the enlargement of the former and the consequent hemiopia and other cerebral symptoms noted in some cases of akromegalia might be due to an attempt by nature to supply the absence of an important structure by compensatory hypertrophy of an allied structure.

A number of cases in which the thyroid gland could not be demonstrated and which presented some, but not all, of the changes found in typical cases of akromegalia were likewise related. In one such case the hands and ears presented marked local asphyxia (Raynaud's disease), while the pain and transient redness developed in the feet upon exertion were suggestive of the condition described by Weir Mitchell under the name of erythomelalgia. In another case, in an aged man, there were cardiac lesions and muscular tremors, with wasting, as in progressive muscular atrophy.

Other cases observed by the speaker in which thyroid atrophy apparently existed were: One case of hypertrophic osteo-arthropathy with emphysema and fibroid phthisis, in a man fifty years of age; one case of scleroderma with cardiac lesions, muscular tremors and mental changes in a women apparently quite aged, who insisted, however, that she was less than forty years old; and one case of unilateral spontaneous gangrene and ulceration of the toes and leg (Raynaud's disease), with bilateral spasmodic vascular phenomena in a woman over sixty years of age. In the latter case certain changes in the fingers and nails existed, which in one finger resembled those of akromegalia, in another finger those of rheumatoid arthritis, in another finger those of sclerodactyle, the nails of all the fingers being curved like those of the Hippocratic finger, as in pulmonary hypertrophic osteo-arthopathy. That this latter condition of the nails and finger tips could be ascribed to interference with nutrition through the circulation was held to be shown by the occurrence in cases of cardiac disease without pulmonary or obvious nervous lesion of fingers indistinguishable, and of which pictures and tracings were exhibited.

Taking up conditions of trophic and vascular disturbance associated with enlargement of the thyroid gland, Dr. Cohen briefly alluded to exophthalmic goitre, myxœdema and cretinism, laying stress upon the fact that as, on the one hand, in akromegalia there might be enlargement instead of apparent absence or atrophy of the thyroid gland, so, on the other hand, in myxœdema and cretinism, the goitre might be lacking, while experimental thyroidectomy, as well as the *cachexia strumipriva* that followed surgical extirpation of the gland, proved that the symptoms were due to a functional atrophy of the gland, whether or not there was hyperplasia of the non-essential anatomical elements. Stress was laid upon the varied vasomotor distubances in all these marked conditions.

In one case of Raynaud's disease an affection, which, so far as the vasomotor phenomena are concerned, is almost an antithesis of Graves's disease, Dr. Cohen

had observed in an anæmic girl, with occasional tachycardia, an intermittent enlargement of the thyroid, just as is observed in certain cases of exophthalmic goitre, and in certain ill-defined cases for which he had proposed the name of *vasomotor ataxia*, which latter could not be called exophthalmic goitre, but in some instances might readily develop into that condition. These latter cases, observed both in males and females, but principally in the latter, and in hysterical subjects more often than in others, showed as an almost constant feature the intermittent presence of hæmocytes in the urine; sometimes, but rarely, transient or intermittent albuminuria as well. In some cases lithuria and oxaluria had been noted, especially in those of rheumatic, gouty, or diabetic families; still more rarely casts or cylindroids had been found. These observation were related with the occurrence of hæmoglobinuria in Raynaud's disease, and of hæmaturia and other hemorrhages, such as purpura, hæmoptysis and hæmatemesis, all of which the speaker had personally witnessed, in Graves's disease; as well as with the occasional albuminuria of the latter, and the polyuria, albuminuria and glycosuria of myxœdema and of akromegalia, and the morbid perspiration and localized œdemas and flushes of all these conditions, and of angio-neurotic œdema—in which latter condition he had also found hæmocytes in the urine during and after paroxysms affecting the throat in one woman and the arms in another. In some of his cases of vasomotor ataxia, a condition which varied much in its severity, from but slight abnormality to such marked affections as those associated with the names of Graves and Raynaud, the author had observed hæmatemesis, with symptoms suggestive of gastric ulcer, anæmia, menstrual irregularities, migraine, transient localized œdema, transient local blushing, permanent dilatation of isolated groups of capillaries and venules, stigmata, local syncope, erythema nodosum and urticaria; in one case there had been transient blindness. In two other cases, in which, however, no thyroid abnormality had been detected, there had been membranous enteritis. Subjective and objective coldness of the knees was marked in one case in which the thyroid was enlarged. In another case, the first observed by Dr. Cohen in a male, there had been great rapidity of the heart's action and intermittent goitre as well, so that the case might well have been called Graves's disease, and doubtless belonged positively in that category. Strictly circumscribed erythema and factitious urticaria could be readily produced in all these cases by writing upon the skin with a probe, or in some instances applying cold to the part. In a colored women with exophthalmic goitre the effect was almost startling.

The connection of rheumatism with Graves's disease, and the heredity of both, was too frequent to be a mere coincidence. In certain cases of rheumatoid arthritis the thyroid gland was found to be enlarged, and tracings were shown of the fingers of an old man with rheumatoid arthritis and arthritic muscular atrophy, in which the parrot-beak pad and nail were shown in the terminal phalanx of the thumb, which was hyper-extended, while the sharpened and atrophied terminal phalanges of the other fingers resembled sclerodactyle, and were almost identical with the tracings from the case of Raynaud's disease. Allusion was made to the tetany of thyroidectomy and the tremors of exophthalmic goitre, some cases of myxœdema, the speaker's cases of scleroderma and of Raynaud's disease, and some of his cases of vasomotor ataxia; as also to the occurrence of phenomena like those of Raynaud's disease in certain cases of scleroderma, the anæmia and the extreme susceptibility to cold, which was a feature of all the conditions described. To complete the list of associations observed, and admitting that they might be coincidental, there were many reported in connection with the occasional occurrence of epilepsy in Graves's disease, two cases of the speaker's, in one of which *petit mal* had developed in an anæmic girl with enlarged thyroid and occasional tachycardia, and in the other, a male, with enlarged thyroid, tachycardia and flushed face accompanied the epileptic paroxysm. The not infrequent termination in phthisis of many of the conditions alluded to might have no other significance than impaired nutrition, but the recent observation of hæmoptyses occurring only during paroxysm in one case of epilepsy without appreciable pulmonary lesion, and in one case of local as-

phyxia with but trifling signs on the chest and a few tubercle bacilli in the sputum, had suggested the thought that vascular disturbances in the lung might be the determining factor. Finally, attention was called to the success of various observers in treating myxœdema by implantation of a thyroid gland, by injections of thyroid extract, and by feeding with fresh thyroids. It was suggested that the same treatment might be of benefit in many of these varied conditions narrated.

The speaker desired to avoid premature assertion of causal relationship, and had therefore made use of the words "associated with," rather than "dependent upon" abnormality of the thyroid gland, in describing the trophic, neurotic, and neuro-vascular phenomena discussed; some of the complicated associations he had been unfortunate enough to meet with were doubtless purely fortuitous. The tendency of diagnosticians was naturally to discriminate among groups of phenomena presenting similarities, and thus to divide rather than unite. Nevertheless, the student of pathology in its broad sense, must be on the alert for commonalty of phenomena, and certainly the very variety of the nutritional disturbances associated with abnormalties of the thyroid gland indicated a profound relationship among them, dependent upon the important metabolic functions of the gland.

The researches of many observers, in particular Horsley, had demonstrated this metabolic importance, and that the secretions of the gland acted in the organism in some way. Dr. Cohen believed that they were in truth chemio-tactic or regulatory, and that individual constitution, heredity, environment, habits, and the like, determined the particular direction in which failure of their function would be manifested. Most certainly an intimate relation existed between the thyroid gland and the visceral nervous system, more especially the vasomotor mechanism. Of course, under the conditions, it was difficult to separate primary from secondary phenomena—the mediate results of the train of action of a mechanism from the immediate results of the influences that had set the mechanism in action.

The main purpose of the paper was to suggest more common observation clinically and at autopsies of the thyroid gland, so that sufficient data might be collected by a number of observers in order to determine what is accidental and what essential.

"Did Not Know It Was Loaded."

A correspondent from Chicago writing to the *Kansas City Medical Index,* maintains the fact that so large a number of physicians in active practice, are deficient in two of the most important branches of the art, viz.:—chemistry and pharmacy—too deficient to be safe,—for the lives of their patients and their own reputations.

He says that recently a second year student of one of Chicago's prominent medical colleges entered a drug store and wanted some "subnitrat of bismuth," at the same time asking the druggist "if it was necessary to have a bottle to put it in, as he did not know what it was."

A graduate from the same school prescribes sulphate of morphia in aqueous mixture with liq. potassæ. The druggist filtered out the precipitated alkaloid and the doctor got no effect from his morphia, —a fortunate thing for the patient that it was filtered as he would have gotten it all at one dose.

A professor in the same college ordered the following prescription:

℞ Ammon. Carb. ..... ℥i
Tr. Digitalis. ..... ℥iii ss
Strychnia Sulph. ..... gri
Elix. Simp. ad ..... ℥iii
M. Sig.—Teaspoonful every four hours, in water.

A very dangerous prescription, as the ammonium salt will precipitate the strychnia and active principle of the digitalis and the patient get an overdose—a bad example to set before his pupils !

Another professor in a prominent Chicago Medical College prescribed a mixture of ammonium carbonate and morphine sulph. in a cough mixture for a baby.

It was not learned whether the child survived or not. The best that the druggist could do was to put a "shake the bottle" label on.

The writer also noticed that several doctors prescribed one twenty-fourth of a grain of murcuric chloride in solution, given (internally) every hour, in a case of diphtheria. This was continued several days and nights—the child died !

THE LIBRARY TABLE.

BOOK REVIEWS.

Handbook of Insanity. By Dr. Theodore Kirchhoff, of Kiel. Pp. 363. Illustrated with eleven plates. New York: William Wood & Co., 1893.

This is one of the volumes of "The Medical Practitioners Library." It is almost equally divided into a General and a Special part, the former giving the anatomical basis and the location of mental disturbances, the classification, importance and mode of action of the causes of insanity, and the signs, course, diagnosis, and treatment of mental disorders. The latter part treats of the simple mental disorders, and the mental disorders associated with permanent anatomical changes in the brain, or with general disease. The work abounds in clinical pictures which are faithfully drawn by a master hand. The descriptions of sufferers from mania, melancholia and paranoia are remarkably good. Their clinical histories, habits, methods of thought, writing and speech are accurately described in detail. The author strongly advocates the early removal of such cases to an asylum.

An interesting feature of the book is the introduction of the plates which are excellent reproductions of photographs of patients suffering from mania, melancholia, paranoia, dementia, etc.

Whilst this is a very interesting and readable book it is to be regretted that such words as "*affects*" and "*concepts*" should so often recur, and that "*wahnsinn*" and "*verrueckheit*" should remain untranslated.

Text-Book of Physiology. By Dr. Foster. Part V. Appendix.—*The Chemical Basis of the Animal Body.* By A. Sheridan Lea, M. A., D. Sc., F. R. S. Sixth edition. New York: Macmillan and Co. 1893. Price $1.75.

The Appendix has been written upon the same lines as in previous editions, except it has been somewhat enlarged.

The term "Appendix" as applied to this volume is misleading, for in reality it constitutes a treatise on the chemical substances occurring in the animal body.

Dr. Lea, who is the author of this work, deserves great credit for a clearness and precision of definition which is not the usual characteristic of works on this subject. Chemists, physiologists and practitioners will welcome this new edition not only on account of its completeness but because it will give them a work that is fully abreast with the times.

Transactions of the American Orthopædic Association. Sixth Session. Volume V. Philadelphia: Published by the Association, 1893.

This association has an active membership of forty-six, together with six Honorary, and nineteen Corresponding Members.

At the meeting held at New York City in September last (1892), thirty-four papers were read and discussed.

Among the more important were those of Dr. Steele, of St. Louis, on "Plaster-of-Paris in Orthopædics"; "An Easy Way to Hold the Operated-on-Club-foot in the Corrected Position while the Plaster-of-Paris Splint Sets," by Dr. Sherman, of San Francisco; "At what Age should the First Treatment of Congenital Club-foot be Instituted?" by H. Agustus Wilson, Philadelphia; "Comparison of Operative Methods in the Treatment of Club-foot," by Dr. Willard, Philadelphia; "Spondylitis of Second Cervical Vertebra, with Report of Cases and Instrument for Treatment," by Dr. Reginald Sayre, of New York.

Mineral Springs and Health Resorts of California. By Winslow Anderson, M. D., M. R. C. P., Lond., M. R. C. S., Eng. San Francisco: The Bancroft Company. 1892.

This work received the Annual Prize of the Medical Society of the State of California in 1889. It contains in addition to the description of the mineral springs and health resorts of California a complete chemical analysis of every important mineral water in the world.

The work contains the names of over two hundred California springs with about one hundred analyses, and two hundred analyses of all the famous springs in America and abroad. Short sketches have been introduced on the fertility and natural productions of California; its historical account, climate, comparative thermometric tables, rainfall, etc., from which it will be seen that the golden shores on the Pacific compare favorably with all the most noted health resorts, whether they be found in the Old or in the New World.

This work abounds in matter that will be read with the greatest interest by students interested in the study of Balneotherapy.

Price List. Parke, Davis & Co., Detroit, Mich.

A compact, handy book of 200 pages, of value to all physicians and surgeons. Not only are prices and method of putting up the goods given, but there is a great deal of useful information contained in the volume.

Capitan (*Repertoire de Pharmacie*) recommends the following treatment for burns. Carefully wash the burned region with boric water or a $\frac{1}{2}$ to 1000 sublimate solution. Cauterize such spots as may be at all ulcerated, with a red hot needle. Cleanse the spots thoroughly and sterilize the hand, with which to apply the following:

℞

Salol	4. o (ʒi.)
Cocain. mur	0.25 (gr. IIIss.)
Vaselin	30. o (ʒi)

Cover with moist sublimate gauze. Over the gauze place absorbent cotton. Change this dressing every two or three days. Meanwhile keep the cotton moist by dropping sublimate solution upon it. If the burns have not suffered previous infection, they heal under this treatment without suppuration or pain.

CURRENT LITERATURE REVIEWED.

THE CHICAGO MEDICAL RECORDER.

The February number contains an article by Dr. Frederick C. Shaeffer on

Skin Grafting on the Cranium,

with the report of an interesting case. The patient, a mill hand, was caught by her hair in a rapidly revolving shaft and completely scalped—the entire skull being laid bare and the pericranium removed in places. Skin grafting was resorted to, 4,500 grafts in all being planted, of which the patient supplied 1800. From the reporter's experience the grafts should be placed close together, thereby forming a stronger skin than when planted farther apart. Dermal grafts with a few fibres of connective tissue form a smooth, soft, pliable skin presenting the characteristics of normal integument; the follicles are preserved, making the patient more comfortable and the new skin more durable. Autodermal grafts are more reliable than heterodermal grafts, providing the patient is healthy; while grafts from a person near the patient's own age give better results than those from one much older or younger. The paper is illustrated with cuts from photographs of the patient taken in different stages of the grafting process.

Dr. James H. Etheridge presents a

Report of Laparotomies

performed during the twelve months. There were in all one hundred and twenty-one operations with fifteen deaths. Celerity, he says, in abdominal operations is most desireable in the avoidance of shock from exposure of the abdominal cavity. Much benefit was derived, he thinks, from attempts at allaying existing active inflammation by rest in bed, laxatives, diuretics and the use of a protracted hot douche, two to four times a day, previous to the operation. The douche should be as hot as the patient can bear, and the improvement of tubal and ovarian disease under its influence was most marked. Pain and tenderness disappeared and, in some cases, total anchylosis of the pelvic organs gave way to a considerable degree. The reporter urges perfect and absolute cleanliness and the use of as few instruments as possible, because of the increased labor of keeping them aseptic. The report concludes with a detailed account of a few of the more important cases. A table of the diseases for which operation was performed is also included.

Dr. Chauncy F. Chapman, in an interesting article on

The Bichloride of Gold Treatment of Dipsomania,

describes the course of the Keely Institute. He points out the fact that, gold having a valence of one or three, a bichloride is a chemical impossibility. He gives the formulæ of the injections used, the principal ingredients of which are strychnia and atropia combined with a small amount of the chloride of soda and gold. Strychnia is recognized as a valuable neuro-tonic, while the atropia seems to decrease the appetite for alcohol. With the patient under the full influence of atropia, alcohol is painful to the dry fauces and mouth, and the systemic effects are no longer pleasant, as the author confirmed by experiments on himself. The method of using the injections at the "Institute" are described in full; and should a patient prove refractory and continue the use of alcohol whiskey in spite of the atropia, he is given a hypodermic injection of apomophia, without his knowledge, which, the writer says, never fails to produce the desired loathing for alcohol. He calls attention to the very large doses of strychnia employed. He has "exhibited hypodermically one-eighth grain given every two hours, by the mouth, until eight doses have been given in the day. This maxium dose is gradually but rapidly reached, beginning with one-fortieth grain hypodermically, until the effects of the drug becomes manifest, when the dose is gradually decreased." The strychnia is often pushed till muscular tremor is pronounced and in some cases antidotes have to be employed, chloral hydrate being habitually used for this purpose. The treatment should also include baths, plain, turkish or electric, massage, good feeding, tonics etc. He believes that the treatment is valuable when properly used; but as it is carried out in the Institutes, with the administrators ignorant of the drugs they are exhibiting, it is dangerous.

Dr. A. Belcham Keyes presents some remarks on

Simple Typhoid,

outlining the treatment as pursued at the Cook County Hospital, where one hundred and six cases were treated during three months, with eleven deaths. Coffee and alcoholic stimulants were used in small quantity, and seemed to do good in the later stages of the disease. "Sponging was found sufficient to reduce the temperature in all cases where it was possible. Phenacetine, antifebrine and antipyrine are considered a menace to permanent improvement and only a means towards a temporary reduction of temperature at the expense of cardiac force where the temperature yielded but slightly to sponging." Calomel as an abortifacient of typhoid is regarded as of doubtful value. Strychnia was used with good effect, lessening the restlessness and jactitation, thereby preserving the patient's strength. Quinine, in six grain doses every four hours, was the only antipyretic given. Salol, nitrate of silver, and carbolic acid apparently gave good results in limiting the tympanites, "but it is impossible to believe that any antiseptic effect was produced on the lesions of Peyers patches." Turpentine with opium did good service in hemorrhage. Tincture of iron and glycerine in large doses were given, in some cases markedly shortening the dry stage.

Dr. Robert S. Nourse reports a case of "Cerebral Abscess" in which there was an area of tenderness complained of in the right temporal region on a level with the top of the right ear and one inch in front of the same; there was also paralysis of the left side. A trephine opening was made six or seven centimeters above and one and one-half centimeters in front of the external auditory meatus. On introducing a grooved director into the brain to the depth of two inches, a drachm of thick fetid pus flowed out. The brain opening was enlarged and a drainage tube introduced. The patient did well for a time but died on the tenth day. At the autopsy a softened area was found around the inferior extremity of the fissure of Rolando and, on tearing this away, an encapsulated abscess was discovered containing three and one-half ounces of thick fetid pus.

The remaining paper is by Dr. John A. Robinson, on "Laryngeal Paralysis."

THE PRACTITIONER.

The February issue of The Practitioner gives the first place to an article on "The Action of Drugs on the Bladder and Genital Organs" by Dr. Lauder Brunton. The subject is considered under three heads. (1), The action of Drugs on the Motor Power of the Bladder. (2), The Action of Drugs on the Urethra. (3), The Action of Drugs upon the Genital Organs.

Dr. Croom in a paper on

Kolpocystotomy in Relation to Chronic Cystitis in the Female,

is of the opinion that few if any conditions short of malignant disease are less amenable to treatment than chronic cystitis in the female. Under the head of local treatment of cystitis he strongly urges against the persistent use of opiates and other anodynes, with a view of relieving the habitual suffering of this disease. "Far from relieving," he says "they aggravate the patient's distress, interfere with her secretions, disorder her digestion, and render her already distressing condition an absolute hopeless one." The treatment offered is a purely local one; the principles on which the treatment is to be conducted are two. First, antiseptic treatment of the mucous membrane; second, continued rest of the hyper-trophied muscular coat.

Bromoform in Whooping-Cough

is the subject of Dr. Burton-Fanning's paper. Bromoform is a colorless oily liquid, with an ethereal smell and sweet taste; it is insoluble in water, and, after many experiments conducted by Mr. Balls, it was most conveniently prescribed thus:

Bromoform	mi.
Pulv. Tragacanth Co	ʒss.
Syrup Simp	ʒss.
Aquae, ad	ʒss.

This forms a pleasant mixture, and the bromoform is well suspended. The appropriate dosage of bromoform is as follows: m ss. for children under one year; m i. up to three years; m ii. up to six years—thrice daily to commence with. If necessary, these doses may safely be gradually increased till they are doubled. Bromoform is decomposed by exposure to light and becomes brown from liberation of bromine, when it must on no account be used. The results have been uniformly gratifying. Usually on the second day of treatment the number of paroxysms are noted as fewer, falling often from about one an hour to one or two a day, and in mild cases ceasing altogether. The attacks are also shorter and less violent; vomiting *always* ceases. Those cases which have epistaxis or other hemorrhages lose these symptoms, expectoration becomes more easy, and bronchitis gradually disappears. Among the cases quoted the following one may be taken as a typical one:

A. L., 2½ years, has had whooping-cough for ten days, having a paroxysm about every hour, accompanied by vomiting and expectoration with streaks of blood; his "breath stops," and once he fell down during an attack. Bromoform (m i.) was ordered three times a day, and on the second day he had only two paroxysms, and no vomiting or stoppage of breath. Afterwards he had none until at the end of a week; belladonna was substituted for the bromoform, when the whoop returned, again, however, to disappear on resuming bromoform, the use of which was continued for five weeks. It is claimed that the drug is of specific power against the main symptoms of whooping-cough—the paroxysmal cough, on which depend the chief dangers of the disease. The doctor says he cannot satisfy himself that the duration of the illness is materially shortened, the average length of the paroxysmal stage in his cases being thirty-one days, but during this time the patients were free from the characteristic cough and its attendant miseries, though these all returned at once, if the bromoform was discontinued within four weeks. The remedy is sufficiently specific in its action to be of the greatest use in diagnosis. The doctor commends it for trial in this common, but by no means trivial, affection of childhood.

"Laparotomy in General Surgery" by Dr. Banks, of which we will speak elswhere, and "Arterial Tension in Angina Pectoris, and its Therapeutical Indications" by Dr. Williams concludes this number.

INTERNATIONAL MEDICAL MAGAZINE

for February contains few articles which call for special attention—nine papers; four of these were read before the American Climatological Association last June.

Dr. Tyson considers at some length. "The Primary or Essential Anæmias"—(1), chlorosis; (2), progressive pernicious anæmia; (3), leukæmia; (4), lymphatic anæmia; (5), splenic anæmia, or splenic psendoleukæmia. The paper contains nothing that is new, it is simply a review of the conditions constituting the anæmias and the management which modern clinical experience has determined to be the most successful.

Dr. Crother's paper

Medical Jurisprudence of Alcoholic Inebriety

is a carefully prepared study of this subject. Some of the facts which have been presented may be grouped as follows:

1. The number of inebriates which come under legal notice is steadily increasing. The methods of treatment are practically failures in every sense.

2. Alcohol is a paralyzant on body and brain, acting upon the senses first, then upon the reason, and finally causing palsy of the higher brain-centers.

3. Many forms of alcoholic injuries occur, of which *trance*, *epilepsy*, *paralysis*, *traumatism*, *insanity* are common.

4. Heredity, training, and surroundings are active forces which lead up to alcoholic excesses.

5. The continuous use of spirits numbs and breaks up the higher brain-centers, and all persons who use alcohol in excess have lessened and impaired responsibility.

6. The natural tendency of all persons who are damaged by alcohol is to lawlessness and crime.

7. The error of regarding all persons as sane who continually poison themselves with spirits results in an increase of crime and the production of a degenerate class. Courts and juries judge of these cases from theory and not from facts.

8. Such cases should be examined by a medical commission, and their conclusions should be final in the evidence.

9. Military hospitals should be built from the license fund and supported by the labor of inebriates sent to it for life or a period of years.

10. All inebriates should be regarded as insane and irresponsible and should be forced to go into military hospitals. They should be treated in the same way as cases of infectious disease are treated.

11. The medical jurisprudence of inebriety promises more for the solution of the alcoholic question than any other means.

THE GLASGOW MEDICAL JOURNAL.

The February number contains nine articles. Of these, we mention, by title, those of Dr. Fraser "On a Case of Sensory Aphasia or Word Deafness, with the Clinical and Pathological Record; with a Case of Functional Auditory Amnesia;" Dr. Marshall "On a Case of Multiple Vascular Nævi, with subsequent Disappearance of many of them;" Dr. Monro "On a Case of Diffuse Gangrene of the Left Lung, due to the Unsuspected Presence in the Bronchus of a Temporary Molar Tooth, which had Accidentally become Dislodged while Patient was under an anæsthetic."

Dr Macphail has a paper on "A Note on Statistics of Enteric Fever." On this subject the only reliable general statement seems to be that the natural variation in enteric fever is so great as to detract very much from the value of statistics as to the results of treatment.

In "Clinical Memoranda," reported by Dr. Jack, on Selected Cases from the Wards of Dr. McCall Anderson's patients, calls attention to (1) "A Case of Pernicious Anæmia—Recovery Under Arsenic—Unusual Complication Terminating Fatally—Post-Mortem Examination;" (2), Case of Cancer of the Lung, complicated with Secondary Cancer of the Liver."

Dr. John Dougall presents "Three Cases from the Wards of the Glasgow Royal Infirmary." (1), Ergot in Diabetes Mellitus; Patient, male; aged 21; specific gravity of urine 1035, acid, and contained twenty-eight and a-half grains of sugar per fluid ounce. During the first six days after admission the quantity of urine passed averaged 226 ounces per day, with a mean specific gravity of 1040. On one of these days the urine measured 310 ounces. The sugar passed daily was close on fifteen ounces. The treatment consisted of a regulated diet, the only medicine given was half a fluid drachm ext. ergot liq., thrice daily. In a week after admission his thirst was entirely gone, the quantity of urine had fallen to about sixty-five ounces daily, specific gravity unchanged. Thirty days after the ergot was commenced it was increased to one fluid drachm, thrice daily, which was continued for two months, then increased to one and a-half fluid drachms ergot, which was continued until he left the hospital, two weeks later, his conditition then being as follows:

STATE ON ADMISSION.

Weight, 8 stone, 12 pounds.
Very weak.
Great thirst.
Much hunger.
Urine, 226 ounces daily.
Sugar, passed daily, 15 ounces.
Skin, harsh and dry.

STATE ON LEAVING.

Weight, 9 stone, 2 pounds.
Much stronger.
No thirst.
Moderate appetite.
Urine, 64 ounces daily.
Sugar, passed daily, 4.9 ounces.
Skin, soft and moist.

---

(2), Biniodide of Mercury in Traumatic Eclampsia.

(3), Case of Poisoning with Bromide of Potassium.

A special point in this case is the lengthened period—three weeks—during which the bromide exerted its physiological action. The presence of bromides, however, have frequently been found in the urine two weeks after the last dose had been taken, and Rabuteau, under similar circumstances, has seen its presence (bromine) persist for a month, thus showing that the bromides are slowly excreted. The symptoms in this case held as due to bromism were the general cutaneous anæsthesia; muscular relaxation; total abolition of the reflexes; lowered temperature, respiration, and pulse; the great somnolence. It has been said that in some cases of bromism the pupils are dilated and uncontractile,

and that the color of the skin and face is unchanged. In this case, however, the pupils were normal, while the face was livid. This latter condition was, no doubt, caused by the reduced cardiac action, and respiration preventing due "æration" of the blood; hence also the subnormal temperature.

THE AMERICAN JOURNAL OF OPHTHALMOLOGY.

The February number contains a description of "A Convenient Ophthalmoscope" by Dr. Howe, of Buffalo. The instrument consists of a concave mirror twenty-eight millimeters in diameter, behind which is a revolving disc containing five plus and five minus glasses, with one opening. A convex lens of the same diameter as the mirror and disc completes the instrument which is said to be "simple, compact and as useful as the ordinary refraction ophthalmoscope."

This is followed by a translation of Gullstrand's paper on the "Objective Method of Diagnosis in Paresis of Ocular Muscles" to which we have elsewhere referred.

Under the head of "Selections" is a contribution by Dr. Seguin on

Eye-Strain and its Relation to Cerebral Hyperæmia.

The writer commences by saying eye-strain, more especially that due to paresis or original weakness of the third and sixth cerebral nerves, produces many symptoms besides cephalalgia and migraine which have lately received so much intelligent attention." "The chief of the symptoms are: Occipital, sub-occipital and occipito-cervical pain and distress; a sense of stiffness in the occipito-cervical region, ("at the base of the brain," as is commonly said,) feeling of fullness, pressure or lightness in the head; sensations of numbness or of formication in the scalp; varying degrees and forms of dizziness (but not true vertigo); inability to read, write, sew, converse, sit at table, to go on the street or into rooms, and even to "think" without supervention of aggravation of symptoms; fear of certain places; insomnia; emotional attacks; pains (differing from migraine) in various parts of the head; and, later, also the multiple symptoms termed neurosthenia." Such symptoms, the writer believes, have too frequently been grouped under "such wholly theoretical diseases" as "*cerebral hyperœmia*" and "*congestion of the base of the brain.*" Dr. Seguin prefers to term them "Cephalic parœsthesia." He offers a preliminary partial grouping of these symptoms. The majority of cases presenting such symptoms are, he thinks, "cases of eye-strain, exhaustion and hyperæsthesia resulting from the persistent use of weak neuro-muscular organs, more especially the third and sixth nerve apparatuses." After mentioning that some cases of cephalia parœsthesia are due to dyscrasic conditions, more especially lithæmia, oxaluria, latent gout, etc., and that lightness in the head and deficiency in power of attention may be due to anæmia, cardiac disease, organic cerebral disease, etc., he returns to a fuller consideration of the "Symptoms of Paresis (Insufficiency) of the third and sixth nerves and attacked muscles."

LIPPINCOTT'S FOR APRIL.

Is mainly devoted to Columbus and the Exposition. The complete novel, "Columbus in Love" is by George Alfred Townsend ("Gath"), and narrates fully and feelingly the great discoverer's relations with Beatrix Enriquez. The leading person of that day in Spain, and some of the chief scenes, are introduced,—Isabella, Ferdinand, the court, the bishops, the fall of Granada, the Inquisition, as well as those most closely associated with the Genoese,—the faithful Nunez, the good prior of Rabida, Pinzon, the sailors, and many more. The novel is fully illustrated.

William Ingleheart tells "What the Publicity Department did for the Colunbian Exposition." A portrait of Major Moses P. Handy accompanies this article.

Julian Hawthorne attempts "A Description of the Inexpressible,—the buildings of the fair; and Frederic M. Bird characterizes "The Religion of 1492" and that of Columbus.

The non-Columbian papers include one by Edgar Saltus on "Sappho;" an installment of M. Crofton's "Men of the Day," covering J. A. Froude, Gounod, Dr. Farrar, General Howard, and Congressman Holman; and an illustrated tale by Annie Flint,—"Abraham's Mother."

ARCHIVES OF PEDIATRICS.

Dr. Rotch begins a paper in the February number on "The Value of Milk Laboratories for the Advancement of our Knowledge of Artificial Feeding." Dr. Osler offers a paper "On Dilatation of the Colon in Young Children" which is merely a reference to a number of cases already reported, together with a few remarks on two children coming under his observation. "Treatment of Bronchial Catarrah in Infancy" is the subject of a very interesting paper by Dr. Carmichael. "Clinical Memoranda" containing seven articles; and two clinical lectures, one by Dr. Jacobi, the other, by Dr. Wharton is the full table of contents of this number.

Dr. Hallister in speaking of the causes and treatment of dropsical effusions, states that: The more obvious causes of dropsy may be enumerated as follows:

First. In cases of hydræmia where, in proportion to its other constituents, the watery portion of the blood is largely increased.

Second. In cases where by imperfect nutrition the walls of the capillaries are weakened.

Third. A more common cause—by reason of increased blood pressure, and

Fourth. A still more common cause—impediment of the venous circulation, and consequent congestion of the capillaries upon which reflex pressure is exerted.—*Chicago Clin. Rev.*

WHY "MUMM" IS SO POPULAR WITH PHYSICIANS.

G. H. MUMM & CO.'S EXTRA DRY is recommended for its purity, its small amount of Alcohol, and its wholesomeness by such eminent physicians as:

Dr. D. Hayes Agnew, Thos. G. Morton, Wm. H. Pancoast, . . *PHILADELPHIA*
" **Fordyce Barker, Lewis A. Sayre, Wm. H. Thompson,** . *NEW YORK*
" **Alan P. Smith, H. P. C. Wilson,** . . . . . *BALTIMORE*
" **J. Mills Browne,** *Surgeon-General U. S. Navy;* **John B. Hamilton,** *Supervising Surgeon-General, Marine Hospital Service;* **Wm. A. Hammond, Nathan S. Lincoln,** . . . . . *WASHINGTON*
" **H. Byford, Chr. Fenger, R. Jackson, C. T. Parkes, E. Schmidt,** *CHICAGO*

" **A. L. Carson, James T. Whittaker,** . . . . . *CINCINNATI*
" **Stanford E. C. Chaille, Joseph Jones, A. W. de Roaldes,** . *NEW ORLEANS*
" **C. B. Brigham, R. B. Cole, Levi C. Lane, J. Rosenstirn,** . . *SAN FRANCISCO*

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M. D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

NO OPENERS REQUIRED. FOR USE IN SICK ROOMS and families. By a recent and most practical invention no openers in future will be required for G. H. Mumm & Co.'s Champagne. To break the wire, bring the small seal to a horizontal position and bend from side to side till one of the wires is broken, pulling upward removes top of cap and wire—done in an instant.

CHAMPAGNE IMPORTATIONS. Custom House statistics of 1892 show G. H. Mumm's Extra Dry to be 75,880 cases, being more than one-fifth of the entire champagne importations and over 9,000 cases more than of any other brand. It is noted for its excellence, purity and natural dryness.

MALIGNANT GRIPPE.

W. H. BURR, M. D., Wilmington, Del.

Notwithstanding I have been keenly scrutinizing the literature relating to the subject of la grippe in its various forms, I have been able to find nothing satisfactory in the way of a clear exposition of the subject in all its details. And nothing at all treating of that particular form or phase of it which I denominate as above. By a clear exposition I mean that which gives not only a perfect description of the symptoms which may occur in the disease, but also a rational idea of the pathology, cause of death when death occurs, and proper treatment based on a thorough understanding of its pathology.

From time to time some mention has been made, in some of the journals, of symptoms of failure of heart and respiration which may occur, and which have occurred in individual cases belonging to the practice of different physicians, but which were promptly met and conquered by the use of digitalis, caffeine and strychnine.

But the typical case of malignant grippe has been ignored and the symptoms of heart failure have been considered only as incidental, and as liable to occur in any case.

Before I describe the typical case I will present a few cases not considered typical of the malignant type, yet in which the incidental complication of heart failure occurred.

Four cases of this character recur to my mind, but as I did not take notes, I shall have to give only a meagre outline of the symptoms.

Case I. Female, æt. 62, a patient of my father, Irish, not very well nourished and a bad feeder.

There were the usual symptoms of invasion and the principal complication was a not very severe catarrhal affection of the lungs. She complained very little and did not seem to be seriously ill, when, on the evening of the fourth or fifth day, F—— was sent for, messenger saying Mrs. K—— was much worse.

Upon his arrival at 5 P. M. he found there had been progressive failure of respiration beginning at 3 o'clock. Patient was blue, respiration almost ceased; hands and feet blue and cold. The chest was immediately enveloped in powerful mustard plasters. Ammon. muriate to the amount of two drachms was stirred up in a bowl with hot water and a little whiskey, and the whole quantity given in the space of an hour, being teased down the throat a little at a time.

The patient reacted and ammon. muriate gr. v., was given every hour for several days, with whiskey and light nourishing food.

Case II. Male, æt. 61. After several days illness in which there was the same complication of catarrhal pneumonia, but in which the lungs were perfectly pervious to air throughout their whole extent, symptoms of heart failure and also of the respiratory center came on. In this case whiskey and nourishing food was given, the stomach interdicting any great amount, and the result was happy as the patient got well.

Case III. Female, æt. 91. After several days illness without any severe complications, only a mild catarrhal affection of the lungs being present, progressive failure of the heart and respiration came on, and despite all remedies and stimulants, patient died.

Case IV. Female, æt 73. Similar to first case, and same treatment was pursued, except the ammon. muriate was not given in so large an initial dose as one or two drachms, but was given for several days in doses of grs. v., every one or two hours. Result, recovery.

But there is an insidious and intensely malignant form of la grippe constantly among us, which not only is not recognized, but the symptoms and pathology of which have never been intelligently described.

This difficulty is increased from the fact that cases of it generally occur sporadically or between the seasons in which the epidemic shows itself. How easy it is, in nondescript cases of disease, to satisfy ourselves and the public by saying "it is a mysterious or anomalous case of malarial poisoning, or typhoid fever." Some time ago a physician writing from some place in West Virginia to a western medical journal, bemoans the fact that he has had seven cases of a mysterious disease, all of which have died.

No one ever attempts to classify these cases, they are simply dead to the attendant and to medical science. I am conversant with four similar cases which I shall denominate cases of "malignant grippe," all of which died and none of which were recognized as la grippe. As nearly as I can recollect, not having made notes of the cases, I give a short description of their symptoms.

Case I. Female, æt. 38; a very near relative of mine. It happened in March, 1891, four or five weeks after the general epidemic for that season had ceased, and everyone had begun to forget all about the disease. The patient was two or three months pregnant, and had been very much run down by previous hard work and mental worry. Was taken with a diarrhœa early in the morning; was weak and miserable. Got up later in the day but the trouble increasing, a doctor was sent for. The diarrhœa became dysenteric in character, and did not respond much to remedies. Finally the bowels became somewhat checked, when vomiting began which became uncontrollable, and in twenty-four hours patient was in a state of collapse and almost given up to die.

Patient reacted and I saw her in the evening about the fifth day from the time she was taken. The bowels were then under control, but she was retching all the time, putting her fingers back in her throat and attempting to vomit despite all remonstrance.

She seemed aware of my personality, but appeared to be in a dazed semi-conscious condition. Pulse was 90 and seemed good, temperature much above normal.

All they were giving her was very poor champagne, one-half teaspoonful, Bovinine gtt. xx, every half hour. I went to bed in the next room, directing that I should be called at 6 o'clock. Was called at 6 A. M., found the patient pulseless, unconscious, with high temperature and commencing to abort.

She died at 3 P. M., stimulants by mouth and under the skin apparently having no effect.

Case II. Female, æt. 28; happened in the following, Summer in this city. Was attended by a friend of mine. It came on in very much the same manner with a dysenteric discharge and ending with progressive failures of the heart and respiration. Diagnosis 'Malignant Typhoid.'

Case III. About two months ago, male, æt. 29, nervous hysterical temperament and with latent tuberculosis, was taken with all the preliminary symptoms of grippe. Pains in back and limbs and chill.

Patient took some cathartic pills and had two free evacuations. Kept at work for one or two days and then quit and sent for me.

I saw him in the evening; temperature 104.° Gave him hypodermic of morphia and atropia and sent him to bed. I had been attending a typical case of typhoid fever a few squares away, and could not disabuse my mind that this was a case of typhoid.

Accordingly, treated him the first few days in a mild antiseptic manner.

The next morning the temperature was down and for several days ranged not over 102°, running down to normal and subnormal in the morning. Patient did not seem very sick but was very nervous and

could not sleep at night. There was not much if any localized tenderness of the abdomen, but complained occasionally of a general uneasiness, and there was the first few days a good deal of rumbling and borborygmus. Complained pretty constantly of pain over the region of the liver. Bowels were obstinately constipated, notwithstanding the use of enemata and calomel.

About the seventh day, the patient vomited his milk undigested and with every successive amount of milk ingested complained of nausea. Vomiting continuing, chicken-water was substituted for the milk, given in tablespoonful doses every half hour with the addition of whiskey. All this time the pulse has been full and fair, becoming somewhat softer with the progress of the case. Temperature ranging from normal to 102°–103° F. Vomiting continued at intervals, but was not very bad. On the morning of the tenth day the pulse went up to 120, which was the first real sign of impending danger. Distressing hiccough set in and continued until death. In the afternoon he vomited a quantity of thin, black fluid which had a peculiar smell, which, though it could not be called fæcal exactly, yet somewhat approaching that odor at times, while at others no fæcal odor could be detected and it had simply a pungent, sweetish, bilious smell. Pulse continued to go up and vomiting continued, the ejecta being thrown up and spit out without any particular effort of the patient. Respirations increased and patient died at 2 A. M., eleventh day.

Two things were noticeable in this case: An anxious look, and peculiar deep respirations somewhat similar to those which occur in the pyrexia of typhoid, although there was no fever to account for them; these were both present from the beginning.

Case IV., in a female, æt 62, rather delicate organization; happened during the last blizzard, beginning Feb. 12th, and ending Monday, 20th. A period abounding in piercing, damp winds from the west which were rendered still more discomforting by being charged with the moisture from large areas of melting snow,—an atmosphere peculiarly conducive to the development of grippal poison. This period is the longest in my knowledge, in which the wind has had that peculiar blizzard-like quality, finding its way into the houses even up to the fireside.

Patient was taken sick Monday, 13th, with the usual symptoms of grippe: Slight chill, pains in the back and limbs, bilious vomiting, general soreness. A few grains of quinine were given, and the trouble was attributed only to a slight cold. Upon special request patient was persuaded to keep in bed the next day; temperature 102° F. For the next few days temperature ranged from normal to 102°–103°; some days hardly going above normal.

Slight nervousness and inability to sleep were the only symptoms complained of. The patient did not consider herself sick, and insisted every day in getting up. Took a fair amount of nourishment. About the fourth or fifth day, had nausea and sick stomach and vomited once or twice. Insisted upon taking some citrate of magnesia, as the bowels had been obstinately constipated. She took some and the bowels moved three times, the discharges being ordinary yellowish in color; this contained undigested milk and smelled badly. Saturday evening, the seventh day, patient having a desire to evacuate the bowels, got out of bed, contrary to orders, to use the chamber and after a free evacuation collapsed and became apparently lifeless. Was returned to bed, rubbed with hot whiskey, hot bottles applied and, after a time, reaction set in. Pulse went up to 120 and temperature 105°. Ninth day, Sunday, temperature reduced, pulse gradually increased, respirations quickened and the patient began to vomit the characteristic black vomit, which came up without much effort being spat out very much in the same manner as in yellow fever. Pulse and respiration increased and patient died 3 A. M. the morning of the eleventh day.

REMARKS.

Several of the above described symptoms might be more particularly pointed out as differentiating the above condition from anything with which it might be confounded.

The typhoid condition is the one with which it probably is the oftenest confounded, although why it should be is hard to see, as there is no manner of resemblance between them. Constipation generally takes the place of diarrhœa, and when the

latter occurs, it is generally the result of taking purgatives and resembles in no respect the characteristic yellow typhoid stool. There is no marked tenderness over the ileo-cœcal regions, but instead you have marked and persistent tenderness over the liver. The fever range is characteristic and different from either intermittent or typhoid. It may run anywhere from normal to 105°, but often in the gravest cases does not go over 103°, and it has no regular time for remission or intermission. There is wanting the typhoid facies and often the face shows little or no anxiety or concern.

The tongue shows absolutely no indication of a typhoid condition, but in some of the gravest cases is moist, soft and clean up to a short time before death. Headache and inability to sleep are marked symptoms.

PATHOLOGY OF MALIGNANT GRIPPE.

Now a word as to the pathology of the disease, and this is a very important consideration in the discussion of any disease condition, for it is only by possessing a rational idea of the pathological condition that we can hope to intelligently direct treatment. What is the cause of the tendency to failure of heart and respiration? It may be the action of the disease poison upon the nerve centres directly, but taking all the different features of the disease into consideration the following seems to us to be a more probable explanation of this unfortunate tendency.

Every one who has at all studied the disease has noticed the fact of the existence of an abnormal condition of the mucous membranes of the whole body. The alimentary canal, from the mouth to the anus, seems to be in a paretic condition, and digestion is for some time almost *nil*. The liver and excretory organs also seem to be functionally at fault. This condition could be produced either by a disturbance of the vasomotor system supplying the absorbtive, digestive and excretive surfaces, interfering with their proper nutritive supply, or to a direct action on the nutritive nerves which supply these surfaces or areas, the only additional conceivable conditions being a direct anatomical change in the tissues themselves.

As the result of one or more of the above conditions, we have the terrible outflow of Asiatic cholera, and in almost all cases it is secretion or excretion in excess or obeyance, that works the death of the patient. In this case the latter prevails and, between the impoverished condition of the blood and possibly the direct poisonous action of the disease germ, we have necessarily impaired nervous energy in the vital centers with consequent death.

There remains much to learn in regard to the pathology of this mysterious disease, but in the meanwhile, in the name of all the humanities and the dignified science of medicine, let it be recognized, and not in the contentment of ignorance call it malaria, typhoid, remittent, etc.

For until a condition is recognized how can we hope to intelligently cope with it. It is like fighting in the dark with a foe we know not of.

TREATMENT.

This explanation furnishes also a rational method of treatment and proves the correctness of that which has been followed by success. If a sufficient amount of food and stimulants can be absorbed, the patient will get well, if not he will die. Alcohol in some cases has seemed invaluable, in others of very doubtful value if not positively harmful.

Quinine, except in the earliest stages, is a very doubtful remedy and must be handled with the greatest care. In many cases it is doubtful whether it does not do more harm than good by increasing the tendency to cerebral congestion. Antipyrine, antifebrine, phenacetine, *et id omnis genus* are very doubtful remedies and it is like playing with fire to handle them. You don't know what minute you are going to have a case of collapse and then the agonizing question comes up, is it the effect of the disease or the medicine added to the disease?

In many cases very little food is taken or digested for days, and in those cases lemons, oranges, apollinaris, ice and whisky seem to do much toward keeping up the strength.

The infusion of digitalis has seemed to commend itself to me. I have used it in a few cases and intend to try it further, giving it early in the disease with a view of possibly averting the tendency to congestion of the mucous surfaces, by contracting the small vessels and at the same time producing its tonic effect upon the heart. But the medicine of all others,

that has commended itself to me in the general run of grippal cases, is ammon. muriate given often and kept up for a long time.

Especially is it useful where there is catarrhal trouble of the lungs, and it is well to combine it with whisky where this agrees with the patient.

In this day and generation, in the effort to supply a satisfactory reason for all things many important therapeutical points are lost sight of entirely. What matters it how a medicine acts if it has the desired effect? The salts of ammonia have suffered in this respect with other valuable remedies. That they have a powerful effect in stimulating the secretive and absorbent system no one who has practised medicine for forty years doubts. If you have got to wait before using them until you find out exactly how they influence those systems, your patients may all be dead, in the graveyard and the muriate will remain still on your shelves.

One of the most remarkable things about the most malignant cases, is that there is very little lung complication, but the full force of the disease is thrown upon the alimentary canal. I have seen one case where there were marked symptoms of meningeal trouble and congestion at the base of the brain. A fly blister at the nape of the neck gave immediate relief.

CLINICAL LECTURES.

RETARDATION OF BRAIN DEVELOPMENT: GASTRALGIA: DEFECTIVE NUTRITION: LOSS OF MEMORY.

HENRY M. LYMAN, A. M., M. D., Chicago, Ill.*

Gentlemen: This little girl is seven years of age, and we are told that she appeared to be healthy up to the time when she learned to talk. At present, her mother says, she does not talk any more than a child two and a half years of age. She is a mouth-breather. From the fact that she has some affection of the Eustachian tube and middle ear, she does not hear as readily as she ought. When a year and a half old she fell, striking on the top of her head. We do not know whether her present condition is due to that fall or not. There might have been a slight hemorrhage at that time which affected the centre of speech. However, it is a case in which the probabilities are in favor of an injury having been received by the brain at the time of the fall. Furthermore, we are told that the child fell over the bed on to the floor, striking upon its head. The presumption is, under such circumstances, that there was an injury sustained by the brain. She escaped without serious apparent injury at that time, nevertheless that does not detract from the fact that a fall upon the head is a dangerous thing.

We cannot always discover the full extent of the injury that has been received at the time of a fall or blow. A little child came once under my observation, that fell backwards off the first step in front of a house, striking the hind part of the head. The injury, at the time, did not seem very severe, but the child died three months afterward with cerebral symptoms. On making an autopsy a fracture at the base of the skull was found. Another child standing on a chair, fell off upon its head and had hemiplegia as a consequence, which was the result of a rupture of a blood vessel. We could go on multiplying illustrations of the dangers that may be induced by a comparatively slight blow or fall striking upon the head.

In the case before you the injury seems to have produced retardation of development. A slight inflammation — not enough to involve the brain in great danger, but modifying its nutrition and producing a slight local inflammation of the membranes—interfered in some degree with the development of the cortex I

*Professor of the Principles and Practice of Medicine in Rush Medical College.

am speaking now of slight causes that are insufficient to produce characteristic fever, general prostration, compression and death. As a consequence of such meningeal inflammation it is a very minor degree of damage that has been inflicted, but when it involves the cortex of the brain it is sufficient to retard development and to interfere with the acquisition of speech; the child remains permanently backward, and is of a lower intellectual order than it would be under ordinary circumstances.

The child does not talk as much as other children, though that may be due to partial deafness. When a child cannot hear well, it is difficult for it to acquire language. It is an obstacle in the way of rapid intellectual progress. The difficulty of hearing is associated with the difficulty in breathing. There is a narrowing of the nasal passages so that the child is obliged to breathe through its mouth. We have a chronic inflammation involving not only the nasal passages, but the Eustachian tube. It has produced a sub-acute or chronic inflammation that interferes with hearing.

The treatment of this case should be relegated to the care of a aurist. The patient should have such operation performed as is necessary in order to breathe freely through the nose, the inflammation of the Eustachian tube and ear being remedied at the same time. This being done the child will doubtless progress more rapidly, and the brain and all the intellectual faculties will be much more readily educated.

GASTRALGIA.

This seems to be a case in which the complaint is principally gastralgia. The patient is a tolerably well mourished man, married, and has a considerable family of children. He says he does not indulge excessively in sexual intercourse, so that the pain cannot be ascribed, as in many cases it can be, to sexual excesses. There are many patients who complain of gastralgia before they commence to eat, when the stomach is empty. You will find in certain cases it is due to sexual excess, but sexual excess has no further relation to the establishment of such a pain than any other form of excessive exertion. You may meet with the same difficulty in persons who sit up late at night and who do not get enough sleep; in persons who are irregular about their meals, or whose business is such as to cause a great deal of mental anxiety. These are likely after a time to have vague, ill-defined pain located about the epigastrium. You can hardly tell whether it is in the back or side, so generallly diffused is it.

This sort of pain is best relieved by removing the cause. If you can get sleep enough for the patient, can regulate his habits of eating and drinking and sexual indulgence, you will, I dare say, without the use of medicine, secure perfect relief. A valuable means for the mitigation of pain is the administration of a little food, a crust of bread, when an attack comes on. I will relate a case in this connection:

A man suffered with gastralgia and found accidentally that a glass of milk would relieve him of the pain, so accordingly he began to drink milk. When the pain came on he would drink milk, but finally the attacks became so frequent that he carried a bottle of milk in his pocket, and kept drinking it every few minutes until his stomach became enormously dilated, and constantly distended with curd, so that this evil was as great as the first.

You must not rely only upon such simple palliatives. You must find out the cause and govern your treatment accordingly. Patients who use much tobacco suffer with gastralgia, and so do excessive tea or coffee drinkers, after a time. It is a common thing for dressmakers—who go from house to house, who are rather irregular in the matter of eating and drinking and their habits of living, who live poorly on some days and on other days live well, who keep irregular hours—to go home late at night after a hard day's work, and make strong tea and drink several cups of it. They poison themselves with the tea. Headache and gastralgia come from the tea and coffee taken in excess. You must urge them to give up drinking such beverages. It is the opinion of some that the excessive use of tea or coffee produces as much personal misery as the alcoholic habit itself.

This patient says that he smokes from eight to ten cigarettes a day. He is a tailor, and people with sedentary occupations suffer most severely with difficulties of this kind. There is a belief that cigarette smoking is worse than ordinary cigar

smoking. I do not know why that should be so if the quality of the tobacco is the same. We will instruct this patient to discontinue cigarette smoking, to change his habits of exercise, and to go out of doors more, and he will probably improve. To benefit his digestion he may take one quarter of a grain of extract of nux vomica, three times a day, and with it a grain of the extract of gentian. During the paroxysms of pain it may be well to add a grain of hyoscyamus, to be taken three times a day before each meal. A tenth of a grain of aloin, or of podopyllin may be added if the bowels are constipated.

DEFECTIVE NUTRITION.

This boy is fifteen years of age. Three weeks before Christmas, he began to have pain in his stomach. He is and always has been delicate. When two years and a half old, his mother says "he caught cold in the spine and was helpless for seven weeks." He could use his arms, but not the lower extremites. When three and a half years of age, he had cerebro-spinal meningitis, and was laid up three weeks with it. He has complained of headache ever since. His appetite is good, but occasionally he vomits his food. He has had steady aching pains in his joints.

Notice the appearance of the patient. His head is peculiarly formed. Observe the prominence of the scapulæ. There is not perfect retraction of the scapulæ when he attempts to draw the shoulders back. The shoulders lap forward a little. The muscles are full but soft, showing that they are not in a state of contraction. It is not natural for a child's shoulders to droop forward in the manner which you see in this patient. It shows a general weakness of the muscles. The serratus magnus muscle should contract vigorously, and should hold the scapulæ firmly against the thorax. It does not act as it ought to. A chronic weakness is apparent in the abnormal prominence of the scapulæ. The bone is not adapted to the trunk as it should be, yet there does not seem to be actual paralysis present. The vertebræ are a little irregular, and their abnormal position gives to the patient a very hollow-chested appearance, which is fictitious rather than real, being caused by the great prominence of the shoulders rather than by any actual falling in of the anterior thoracic wall.

These symptoms we may account for in part by the attack of cerebro-spinal meningitis which the patient had when he was three and a half years of age, and it is very probable that the nerves were then so damaged that they have not since been able to convey proper trophic impulses and tonic influences to the muscles, so as to keep them in a healthy state; yet there is no complete paralysis. It is damage not destruction, that has occurred.

The pain experienced is very irregular and widely distributed; he also complains of tenderness on pressure. The vasomotor nerves are deficient in tonic power. When I drew my finger over the front of the chest (left side), it was followed by the appearance of a purple line on either side of it. The same appearance can be had on the right side. That is consequent upon a sluggish action of the vasomotor nerves that control the circulation of blood in the skin. It is not an evidence of any specific disease, or of any particular condition other than that of general vasomotor exhaustion. It occurs in various disorders. You see it in the introduction of measles, scarlet fever, tubercular meningitis and diseases generally exhaustive in character. The mother says he wets his bed at night, which is another evidence of nervous irritability. There is nothing characteristic about the respiratory sounds.

The patient does not have the appearance of one who has chronic renal disease. In that disease there is a peculiar pallor. I should hardly expect to find renal disease in this case, but still the urine ought to be examined to ascertain whether there is any disease of the kidneys, and examination shows it to be normal.

The joint troubles are of the nature of aching pains without swelling. You will frequently hear patients complain of "growing pains." "Growing pains" are simply neuralgic pains felt about the joints and sometimes in the muscles of different parts of the body. Sensitive nervous children are liable to neuralgic pain. When it is really rheumatism, it declares itself in the form of difficulty of moving the muscles, a cramp, a torticollis, or something of that kind.

This patient has a slight chorea. There is a little nervous twitching about the

arms. The mother further tells us that he has no desire to sleep. There is no history of rheumatism in the family, nor of tubercular disease; no scrofula, and no eruptions upon the skin. Those facts militate against hereditary syphilis and scrofula.

We do not succeed in putting our fingers upon a definite single lesion or disease, but must take the case as one in which there is a general disorder in nutrition and, consequently, deterioration of health. The shape of the patient's head alone is sufficient to indicate it. The undue prominence of the forehead and the bulging aspect of the head itself are sufficient to mark the case as one of defective nutrition. It is not severe enough to constitute "rickets." There are no syphilitic manifestations. We have evidences of imperfect development of growth and nutrition of the body at large. The history of feeble digestion points in the same direction. When children grow up with bad stomachs it is not to be expected that they will mature normally and healthily as other children do.

Then it is well to observe the expression of countenance. You see how this boy keeps continually wrinkling his forehead. When you see that you inquire into the condition of the eyes. It is due to eye strain sometimes. The patient has difficulty in fixing the eyes upon certain objects. His eyesight is poor. He should have his eyes properly attended to by an experienced oculist, and all defects of vision should be corrected. A large number of these cases are due to a malformation of the skull. Persons with perfectly formed skulls do not have bad eyes. When there is an imperfect development of the skull, there are deformities of the ocular globe. The patient, for instance, may be astigmatic, a condition which interferes with easy, distinct vision. This wrinkling of the forehead must be corrected by proper glasses. Many a child suffers with headache when it has uncorrected ocular defects. Many of these defects can be very much aided—in fact, entirely relieved sometimes—by the use of proper glasses, but it requires careful observation and special delicate adjustment to get glasses that will exactly correct the errors. I know this from my own experience when I commenced to wear glasses a few years ago. I found that a single examination was not enough, that it was necessary to make repeated examinations to correct the defect. Even the oculist himself cannot always tell the exact amount of correction that is necessary. The states of the eye vary from day to day. What is sufficient to-day won't be sufficient next week; so much depends upon the transient states of the nervous system, the amount of tone in the muscles, and the amount of vigor in the nerves which vary from day to day and from week to week; but with intelligent assistance on the part of the patient the oculist can usually succeed in correcting the defect; and the comfort that proper eyeglasses give to such persons must be experienced in order to be thoroughly appreciated.

Now, a great deal can be accomplished for the relief of this patient by proper adjustment of glasses for his eyes; then he must be treated on general principles to invigorate his general health by assisting digestion. The patient must be placed under the most favorable conditions for nutrition, and then little by little, he ought to improve and gradually outgrow many of his defects. Associated with this treatment should be properly arranged methods of gymnastic exercises with dumb-bells and pully weights, that will expand the chest and invigorate those muscles that throw the shoulders back.

LOSS OF MEMORY.

The next patient, a woman, is forty-eight years of age. Nine years ago she was confined, got up within a week and went about her household work for two or three days; then she went to bed and lay there for six weeks in a stupor. She did not have sense enough to nurse the baby. Her parents had to feed her. She has had two children since then, but no such profound stupor. Sometimes, however, she will sit and stare for a long time at nothing. She is weak and now unable to do her housework, and is steadily growing worse. Occasionally she has lucid intervals. She was born in Scotland, and left that country when nineteen years of age. She does not remember the number of the house nor the street she lives on.

A peculiarity which is quite apparent in many cases of deterioration of the memory, is that patients remember incidents of their early life better than those of re-

cent occurrence. The same is true with this patient. She remembers the place where she was born, and of coming to this country when nineteen years of age; but she is not able to give an account of recent events. She is unable to tell us the number of children she has. That is a very interesting characteristic of loss of memory which is dependent upon deterioration of the brain. We see it in a more or less marked degree in all elderly people as they advance in years. Their memory of early life is perfect, but the events of last week or last year are almost forgotten. It is difficult for many elderly people to remember or talk of things that have occurred within the last five or ten years.

Dr. Rush tells us what he observed in the epidemic of yellow fever in Philadelphia, 100 years ago. He had an immense practice and saw a great many patients. Among them were many Swedes who had lived for many years in Philadelphia. Having migrated to this country in early life, they had learned to speak English and consequently had almost forgotten to speak their native language. For fifty years or more they spoke English. He noticed that those old people who were striken with yellow fever would recount incidents in the Swedish language, a language which they had not used for many years. It seemed as if their experiences or impressions of later life had been obliterated and that original impressions came once more to view. When, by age or by certain diseases deterioration of the function of the brain is manifested, the loss of memory shows itself in this way. Then again, the loss of memory declares itself in regard to the names of things and of persons.

With regard to action, it is something that is bound up in our nature. We form habits of walking, of seeing, eating, drinking and of daily life. Our professional occupations become habits that are ingrained in our nature. These things we do not forget as we do the names of things that are arbitrarily fixed. An apple is a sort of sign to designate a certain thing. When the brain becomes deteriorated by disease, and an apple is presented to the patient, she cannot tell you what it is. She has forgotten the name of it. If you let her take the apple in her hand she has not forgotten that it is good to eat. She has not forgotten the action suggested by the sight of the apple. The name goes first, but the action that is connected with the thing is not forgotten. These peculiarities are characteristic of a deteriorated brain, which seems to be the case with the patient before us.

There is some grave disease involving the brain. Nine years ago when the patient gave birth to a child, she passed into a stupor and remained in that condition for six weeks. Whether she had puerperal fever or toxæmia, or not, we do not know. It is not improbable that there may have been some toxic influence operating on the brain that produced the state of stupor that persisted. We know conditions of toxæmia do produce such stupors. It is observed that in certain old cases of cerebral syphilis, patients pass into a state of stupor, the conditions of the brain being induced by various causes of a cachectic character which we do not understand exactly. But the patient is in a cachectic condition and may lapse into a state of stupor and remain in that condition for weeks or months.

Dr. Gardner, of the Glasgow University, has recorded a case in *The London Lancet*, of a woman who remained in a state of stupor for three months, then she emerged from it the same as this patient did. During all that time it was necessary to feed her with a spoon. There was some twitching of the eyelids, and the patient appeared as if she knew that persons were near her. She knew her husband when he came to see her, and manifested her consciousness of his presence by certain motions of the eyelids. But consciousness is absolutely and entirely obliterated in many of these cases. As a consequence of such disorder of the brain cortex having remained after the patient recovers from the state of stupor, it is very apt to leave the brain in a permanently deteriorated state, and the patient may lapse suddenly or gradually into what is called *terminal dementia.*

Dementia is a state in which the patient has perhaps good general health, but the thinking power of the brain is pretty much abolished. The patient lapses into a state approaching that of an animal that is deprived of its cerebrum. The degrees of dementia vary with the profundity of the lapses from the normal standard of

health. That seems to be the case here. The patient is not, perhaps, entirely demented, but is on the way towards terminal dementia.

These cases are also very intractable. It is difficult to cure them, yet they can be relieved, if not entirely cured, sometimes. The method to pursue is forcible feeding. When they are in a state of stupor it becomes necessary to feed them artificially. They must be fed with milk, eggnog, and every kind of food that can be made into a thin paste. It is necessary to feed them in this way sometimes for weeks or months. In addition to forcible feeding, they must be stimulated, and the stimulation which comes from electricity is of a useful character. They may be sometimes aroused by it and saved from the condition of terminal dementia which is almost inevitable otherwise. These cases are hopeful if you can get them to take nourishment in large quantities; especially if, in addition to taking nourishment, they improve in flesh. But, when a patient is conscious and has suffered in this way for nine years, it is doubtful whether complete restoration to health can ever be secured; still it would be advisable to feed her well, to administer arsenic, phosphorus and strychnine. These three agents, which promote nutrition and increase the circulation of the blood in the cortex of the brain, would be useful in this case. A long course of such treatment might produce a good effect.

COMMUNICATIONS.

PARALYSIS OF LARYNGEAL MUSCLES, WITH CASES.

WM. CHEATHAM, M. D.*

The larynx has nine muscles, four pairs and a single. Besides these there are three pairs belonging to the epiglottis—the thyro-epiglottis, inferior aryteno-epiglottis, and the superior aryteno-epiglottis. The posterior crico-arytenoidei widen the aperture of the larynx. The crico-arytenoidei lateralis and the arytenoidœus, assisted by the muscles of the epiglottis and the ary-epiglottis, close the aperture of the larynx. Those governing the pitch of the voice are the crico-thyroidei, assisted by the crico-arytenoidei postici, making the cords tense. The thyro-arytenoidei externi shorten, relax and bring the vocal cords together.

The nerves of the larynx are the superior laryngeal and the inferior or recurrent laryngeal, both branches of the pneumo-gastric. The superior laryngeal supplies the mucous membrane with sensation and the crico-thyroid, the thyro-epiglottic and the ary-epiglottici muscles; the other supplies the other muscles; the ary-tenoidœus receiving fibres from both.

Neuroses of the larynx may be either sensory or motor. Those of sensation may be anæsthesia, hyperæsthesia, paræsthesia and neuralgia.

Gottstein and Lefferts have given a clinical classification of paralysis of the muscles of the larynx, and Mackenzie a pathological one.

I have seen cases of paralysis of the recurrent laryngeal unilateral and bi-lateral, of the adductors unilateral and bi-lateral, of the abductors unilateral and bi-lateral, and of the aryte noidœus.

One case of hysterical paralysis of the adductors, which I believe I reported to this society before, was in the person of a merchant from one of our interior towns. As in most similar cases the muscles of the lips were also involved. A strong interrupted current with one pole in the larynx soon restored him his voice. I have seen several cases in females; some of them hysterical and some catarrhal. Rheumatism may produce it or it may be toxic in character, depending upon lead or arsenic; lead here affects the adductors alone as it does the extensors of the forearm. Anæmia is a common cause. I have seen some times persistent, but more often intermittent, paralysis of one or both adductors in cases of lung phthisis, lasting

*Professor of Diseases of the Eye, Ear, Throat and Nose, Louisville Medical College.

for several years. Diagnosis is usually easily made with the laryngoscope. Prognosis in adductor paralysis is usually favorable. Emotional influences give relief frequently. A brush applied to the larynx or sometimes the simple act of laryngoscopic examination gives relief. Mackanzie cites in his book a case taken from Herodotus, who speaks of a son of Crœsus who was dumb, but whose voice was restored when some one not recognizing his father was about to kill him.

Paralysis of the abductors is a much more serious matter. Here we have the "Gate of life" about to be closed. The cause may be neuropathic or myopathic. In three cases seen by Mackenzie during life, changes were found in the muscles after death, while the nerves and brain were normal.

My object in presenting this paper this evening, is to report four cases. One positively paralysis of the posterior crico-arytenoidei; another I am not so positive of, as it is in the person of a child but six months old, rendering a laryngoscopic examination almost impossible; and two cases of paralysis of the recurrent laryngeal nerves the result of large aortic aneurisms. The last two cases mentioned died in a few days after I saw them, of rupture of the aneurism. In these cases no operative interference was indicated as the cords took the "cadaveric position" in which voice is partially lost but respiration not much interfered with. These are all the cases of this trouble I can recall as having seen.

The child referred to above was brought to me about one week ago. The mother said it had had the trouble all its life. As I stated before, the child is but six months old and its only trouble is on inspiration; expiration is perfectly free; symptoms worse when asleep. The noise it makes then in breathing can be heard all over the house. Its cry and crow are natural; it has no trouble in feeding; the mother says it is as healthy as any other child. After several efforts I could see the epiglottis and the vestibule of the larynx; the epiglottis is an exaggerated omega shape; I could discover no growth of the larynx. A growth of the larynx could give about the same symptoms. I have seen two similar cases in babies, or cases with similar symptoms, which were relieved by pulling the tongue well out, or by holding the children with their faces down; both of these children had trouble in nursing; this child has none. The present symptoms are those indicative of paralysis or paresis of the cord abductors. I have never heard of a congenital case unless this is one. Some one may suggest anæsthesia for a laryngoscopic examination. There would be great danger attending it and any one undertaking it should be prepared for an intubation or a rapid tracheotomy.

The second case is in a woman forty-five years of age, otherwise healthy; she has been examined several times by different doctors and no cause for the abductor paralysis discovered. The trouble has been coming on for months; she has been treated for hysteria, so she says, having taken a gallon or two of asafœtida and valerian; the breathing is so bad at night that policemen have rung the family up and asked if any one was being murdered. When she came to see me about six weeks ago I found expiration free, but inspiration very difficult; voice not much affected; she had had electric and other treatment with no relief. Symptoms made worse by exertion. The laryngoscope gave a perfect picture of paralysis of the post-crico-arytenoidei; the cords were nearly together; the chink enlarged somewhat on expiration, but nearly closed in inspiration; the shape of the cords, and the difference in the rarity of the expired and inspired air accounts for this. I suggested that she again try electricity and add to it hypodermatics of strychnia nitrate; she reported in a few days with her trouble much increased, the cords looked some thickened and red; her lips were a little blue; she could not sleep well but while talking to any one she would fall asleep. Believing the case now to be quite a serious one I suggested to the family either intubation or tracheotomy; they, of course, preferred the former.

This narrowing of the glottis leads to much damage in other organs. This interference of change of gases in the lungs drives the blood back to the right side of the heart, resulting in much damage to distant organs. Intubation was done four weeks ago. I inserted, with but little trouble, an adult hard rubber tube. Vulcanite is better for the adult tubes, especially when used in such a case as this, as there is no membrane to plug them consequently not so

liable to be coughed out, weight to prevent it not being necessary. Calcareous deposits are not as liable to form on them, consequently they can be worn longer without a change being necessary; the weight being so much less, they are not liable to irritate the vestibule. The patient complained a good deal of the tube for several days; said she now gets too much air. There was some soreness on swallowing for a few days. Temperature for four or five days was 100. To-day, Feb. 21st, temperature is normal; there is but little soreness on swallowing, and she says she sleeps better than for months; all drowsiness has disappeared, and color is good. She says she feels like a new woman; she eats solids and semi-solids sitting erect, but has to take fluids with chest lower than the rest of the body.

What is the future of this case? I am inclined to use the intubation tube as long as it can be worn, changing the tube for cleansing and to utilize new points of pressure every four, six or eight weeks, by this hoping in some months to get the cords fixed in the "cadaveric position," or if this can not be done to nick or cut through each cord, then put the tube back. Whether or not this can be done without a preliminary tracheotomy I cannot say. I will of course try it later on. I know of no measure of relief that will not destroy or partially destroy the voice. With the tube in position the patient can now make herself understood across a large bedroom. I believe then that the patient can, should no accident occur, by operative interference get free breathing with partial loss of voice. No book, that I know of, speaks of intubation for the relief of this difficulty. Tracheotomy is advised. Intubation has been successfully used in similar cases by O'Dwyer and others. Dr. O'Dwyer for one of his cases had a cylindrical tube made so as to get more lateral pressure.

These cases are fortunately rare. A majority of them die of their own neglect, refusing operative interference, and others of neglect of their physicians who turn them away as hopeless. A strange coincidence, if the baby's case is one of abductor paralysis, is that both cases live in the same neighborhood, within a square of each other.

Mr. President, while on the floor and speaking of paralysis, I would like to state that in the last ten days I have seen two cases of one sided mydriasis, one of the cases with myosis of the fellow eye, one case of right third and fourth nerve paralysis, one of left third nerve paralysis with atrophy of the right optic nerve, with some of the muscles of deglutition involved, and another with paralysis of the right third, fourth, fifth, and sixth nerves. I also have, besides the patient reported which promises to be a lengthy one for intubation, a child three years old, who has been wearing a tube twenty-three weeks for a growth of the larynx, the tube staying in at one time seven weeks without being changed; and a woman with phthisical laryngitis who has been wearing a tracheotomy tube for nine months with perfect comfort.

TREATMENT OF BILIARY COLIC WITH GLYCERINE.

H. REASONER GEYER, M. D., Norwich, O.

Surgeons are now removing biliary calculi and some successful cases have been reported.

Before so serious an operation is performed all therapeutical means should be exhausted. In many cases surgical interference is not necessary. A patient may have an attack of biliary colic and suffer severe pain, which may be relieved by therapeutical means.

I wish to call the attention of the profession to a remedy which I have been using for the relief of biliary symptoms, and to report the following cases treated with *glycerine.*

Case I. Mrs. H.; widow; age fifty-three; of stout build. The patient has given birth to six children. Health good until menopause, which occurred at the age of forty-five. Since then patient has suffered more or less with various troubles. In January, 1891, the patient had quite a

severe attack which was diagnosed as biliary colic. Subsequently she has suffered recurrences at intervals of about six or seven weeks. Morphine had to be used quite freely to relieve the pain. I was called to see patient in July, 1892, and found her suffering with severe pain in the epigastrium, radiating to right side; also in the back near spinal column. Nausea and vomiting were present. I immediately gave her a tablespoonful of glycerine. The vomiting ceased and in ten minutes the pain was considerably relieved. Repeated the dose in twenty minutes, and in one-half hour from first administration, the patient was free from pain. When relief had been afforded, a severe rigor set in which lasted for some time. Ordered a teaspoonful of glycerine to be given every three hours. Next day the patient was able to be around, and without suffering from the headache and nausea which followed the use of morphine. There was marked tenderness in the region of the gall-bladder, liver somewhat enlarged and patient very much jaundiced. Stools of clay color. Ordered ¼ grain calomel pellets to be given three times a day, until bowels moved freely. In ten days the icterus was gone and the patient well as usual.

In two weeks she had another attack, which I relieved with glycerine in the same manner as above stated. No more attacks occurred until Sept. 30. This was unusually severe. Renewed the glycerine as above described, and relief followed in thirty minutes. Then I ordered

℞ Potass Citrosi.....ʒii
Glycerine.....ʒiv
Sig.—Teaspoonful three times a day.

This was given for a few weeks and now the patient is taking but one teaspoonful a day. Up to the present time, March 1st, 1893, there has been no return of the symptoms.

Case II. Mrs. F.; age 66; married; has given birth to nine children. Health always rugged until menopause. For last ten years has had spells in which she suffered pain in epigastrium with nausea. Vomiting would generally end the attack. On November 4th, I found her suffering severe pain in epigastr um, radiating to right side, very much nauseated, and vomiting quite frequently. From the history of the case and the symptoms present, I diagnosed biliary colic. I gave a teaspoonful of glycerine, repeating the dose in fifteen minutes, and in one-half hour the patient was free from pain.

As soon as the pain subsided the nausea ceased and the patient had a chill. Next day I found her much better; liver slightly enlarged and very tender to pressure in region of gall-bladder. No jaundice present, stools of clay color; senna was ordered to move the bowels and nothing further was given. Soreness remained several days. There has been no return of the symptoms up to date, a period of four months.

Case III. Mrs. B.; age 57; mother of seven children; of spare build, but has always been very rugged. On December 15th, 1892, was called to see her, and found her suffering with severe pain in region of the liver. Nausea and vomiting present. Relieved her with glycerine as stated in Case 1. Next day found tenderness in the region of the gall-bladder. No jaundice, stools clay colored. No return of symptoms so far.

Case IV. Mrs. W.; age 64; has given birth to seven children; sparely built; always enjoyed good health. Has had what she called "cramp colic" several times. Was called to see her in January, 1893. Found her suffering severe pain in the epigastrium, very much nauseated and had vomited several times. Tenderness on pressure in the region of the liver. Relieved her with glycerine as stated in Case 1. Next day I found her much better. No jaundice present. Stools clay colored. Urine very offensive and high colored. Nothing further was given and the patient made a rapid recovery.

Dr. Albert Brubaker says that *Spasmodic Croup* in children, coming on suddenly at night, is often due to impaired digestion brought on by eating some heavy food just before retiring. If the stomach in these cases be emptied by an emetic, it will be found that the croup will also disappear.—*Cal. and Clin. Rec.*

Garlic is the latest remedy guaranteed to cure cholera. This ought to do it, sure! What well-bred and self-respecting bacillus of standing in the pathogenic fraternity could face such an enemy?—*Ex.*

A CASE OF GONORRHŒAL RHEUMATISM.*

A. M. VANCE, M. D., Louisville, Ky.

The patient is a friend I have known for a number of years. Some five or six months ago, he came into my office walking with great difficulty, said he did not know what was the matter, his feet were badly swollen and very painful. I asked him if he had ever suffered an attack of gonorrhœa, and he said yes, that he contracted gonorrhœa about three months previously and had been treated by various physicians, by electricity, etc. I examined him carefully and made up my mind that he had a typical case of so called "gonorrhœal rheumatism." I informed him of this fact and he wanted to know what could be done for it. I gave him a very blue prognosis. He went over to French Lick for a week—as I advised him to take a little rest.

When he came back he went to Dr. Palmer, who cured the gonorrhœa so far as any special symptoms about the genitals were concerned, but his feet were no better. He then employed a homeopathic physician, stating that Dr. Palmer had given large doses of iodide of potassium which he sustained without any bad symptoms at all, and the second doctor told him that his experience was, that when a man could stand such large doses of medicine without any effect, one of the orifices of the body was at fault, either the rectum or the urethra. He examined the penis and finding that all right, made an examination of the rectum and told the man that he found several "folds" or "pockets" which should be removed. He was sent to the Norton Infirmary and the lower part of the rectum excised.

About three months afterward he returned to me, and I found him in even a worse condition than upon his previous visit. I told him that I could not possibly do him any good unless he would take absolute rest; that I thought if he would go to the infirmary for about sixty days, I could benefit him a great deal. He considered the matter for a day or two and finally consented. He went to the infirmary and I put on a pair of plaster boots reaching to his knees, and commenced giving him iodide of potassium. I want to state that he gave a history of syphilis in years gone by and I thought some of the trouble was possibly of a specific character. I gradually increased the dose of iodide of potassium until he took about 400 grains per day, and he progressed very favorably. I also gave him bichloride of mercury in $\frac{1}{30}$th grain doses, keeping him in bed for about thirty days; at the end of that time I removed the plaster boots and found that his feet had returned to their normal condition so far as swelling was concerned. Tenderness had disappeared entirely in the right foot, but the left heel was still tender on pressure. I kept him quiet two weeks longer, and at the end of six weeks he is walking about and I think his ultimate recovery is assured.

The point of consideration in the case with me is, the kind of medicine to be used in these sub-acute and chronic cases of gonorrhœal rheumatism. I believe that iodide of potassium is the proper remedy. The disease is probably a plastic deposit around the nerves and the treatment should be directed to its absorption just as you would in chronic rheumatism or syphilitic deposits. The reason he responded so readily to iodide of potassium may be the fact that the trouble was partly syphilitic in origin, but I have had the same result in other cases where there was no specific element.

*Reported to the Clin. Soc. of Louisville, Jan. 23, 1893.

The Provident Bounty Association, of London, has published a prospectus recommending itself to the patronage of all families, and especially to that of young married couples. Its object is to insure married people against twins and triplets. A married man expecting to become a father, the prospectus states, must deposit £5 to become a policy holder. In case the policy holder's wife has twins, he will receive £50; in case she has triplets, £75. The conditions of issuing policies are simple, and are intended to appeal especially to the lower middle class, including young bookkeepers, shop clerks and small tradesmen.

RUPTURE OF THE UTERUS FOLLOWING ADMINISTRATION OF ERGOT, WITH REPORT OF CASE*

H. H. SUTHERLAND, M. D., Herrington, Kan.

Early in the summer of 1888, I was requested by Mr. C—— to prescribe for his wife. He gave me the following history: Age 28 years; mother of two children, age 5 and 7 years; small; rather delicate constitution, although health previous to last confinement was good; menses irregular, profuse and quite painful, she being obliged to keep her bed several days at each period. She had heavy bearing-down pains in the pelvis, which were aggravated by standing. She suffered one to three attacks of uterine colic during each inter-menstrual period, which confined her to bed one to two days at each attack. With her menstrual trouble and uterine colic she was obliged to keep her room the greater portion of her time, being almost completely invalided.

Although I frequently urged the importance of an examination and a better knowledge of her trouble, the above history was all I could secure.

About February 1st, 1890, she conceived and soon after began vomiting, which continued until she was so reduced in strength that she was no longer able to leave her bed. After trying all known remedies without success I decided, to try cocaine, although at that time I had no knowledge of it being used in like cases. It had the desired effect and, by the judicious use of a weak solution, she was enabled to retain nourishment. In fact, the vomiting almost ceased. But a new difficulty presented itself—ptyalism in its worst form. Any attempt to arrest this would produce nausea and vomiting.

She increased in strength and was fairly well until in May, in the fifth month of pregnancy, she suddenly began flooding and came near losing her life. I was absent at the time, and Dr. N—— was called in. He gave ergot to control the hemorrhage and with partial success. The next day I found the following condition: Flooding came on very suddenly during the night, the bed clothing and mattress were saturated and the blood, passing through, formed a pool on the floor. Patient colorless; pulse very rapid and weak; still bleeding a little; constant ptyalism and a return of the vomiting.

In her exsanguined state, and with a pregnancy of about five months, I believed it would be dangerous to tampon and wait for dilatation. Therefore, I decided at once to dilate and empty the uterus of its contents. Dr. N—— informed me that at first the os was considerably dilated, but that the ergot had caused it to contract. I found it very rigid. After considerable effort I succeeded in introducing two fingers and removed the body of the fœtus, leaving behind the head and placenta. My fingers being tired, I asked Dr. N—— to relieve me. In a few minutes he removed the head and placenta, but, to our surprise, he had broken the skull, and the sharp edges of bone had cut through the anterior wall just inside the internal os, making a utero-vaginal fistula.

Our patient was in a critical condition for the next twenty-four hours; ptyalism continued for two weeks; convalesence was slow and incomplete.

In July she was able to be up and about the house. He health was worse than before the pregnancy. Assisted by Dr. N—— I closed the utero-vaginal fistula and also repaired an old bilateral laceration of the cervix which had occurred during a labor five years previous. Improvement was marked from that time.

At present her health is completely restored, and for more than eighteen months she has done all of her housework —including the washing. Her menses are normal and the attacks of uterine colic have practically ceased. To use her own expression, "life is now worth living."

While there are some who condemn operations on the lacerated cervix, I believe it has done as much to relieve suffering as any other one operation on the female pelvic organs. Had I been permitted to learn the true condition of the cervix and to have repaired the injury, I am confident my patient would have been spared all her trouble, both before and after conception, and would have gone to full term.

*Proceedings of the Western Association of Obstetricians and Gynecologists.

There are a few points of interest:

(1.) The persistent vomiting, controlled by cocaine and followed by ptyalism, which continued for some time after abortion.

(2.) The use of ergot to control hemorrhoge, instead of emptying the uterus of its contents.

(3.) The dangers which may result from the indiscrete use of ergot.

(4.) The danger in crushing the skull in order to remove it.

(5.) The restoration of health; the cessation of uterine colic and menstrual trouble by repairing the previously existing lacerated cervix.

SOCIETY REPORTS.

THE CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting, February 21st, 1893.

Dr. J. M. Krim, Vice President, in the Chair.

CARCINOMA OF THE MAMMÆ.

Dr. W. O. Roberts: The patient from whom this specimen was removed is sixty-seven years of age. Four years ago she had a growth that came on the end of her tongue, which she said when first noticed was as large as a pin's head; it steadily increased in size. One year after its appearance it was removed and was then about the size of the first joint of her little finger. It bled very freely at times. Since its removal there has never been any appearance of the trouble about the tongue.

The growth which I have here was first noticed in the breast last fall a year ago; it was then about as large as an almond; it has steadily increased in size up to the present time, and there is marked retraction of the nipple. Her father died of cancer and two of her sisters have had operations performed for cancer. This tumor occurred without any history of injury whatever. She had, however, in earlier life some trouble with this same breast during the nursing of her children. I do not know how many children she has had, but with each of them she said she had more or less trouble with this breast, but never had an abscess. This case is very much like several others which I have had recently, where there have been several cases in a family of malignant disease.

The breast was entirely removed, of course down to the pectoral muscle; the fascia was carefully dissected up and the axilla thoroughly cleansed.

Last summer, just before the Congress of American Physicians and Surgeons, Dr. John Chiene, of Edinburgh, stopped over in Louisville, on his way to attend the Washington meeting, and he had with him an article from his assistant, Mr. H. J. Stiles, of Edinburgh, concerning the method of determining whether or not all the malignant growth has been removed in an operation for cancer of the breast. I thought possibly it would be of interest to the members of this Society if I would read an account of Mr. Stiles' method. The extract I have here is taken from the "American Text Book of Surgery."

"Mr. H. J. Stiles, of Edinburgh, has recently devised a method for detecting carcinomatous tissue, so that the surgeon at the time of the operation can ascertain whether he has removed all the carcinomatous tissue, or whether some portion still remains in the wound and should be removed. His method is as follows:

(1), Mark the position of the heart by a slight incision extending both on breast and on the skin which is to be left. This is to enable the operator to identify the position, and therefore, the corresponding surfaces of the breast and the wound after the removal of the breast.

(2), Wash the breast in water to remove all traces of blood. This is important, because, after treatment with nitric acid the blood becomes blackened and difficult to remove, and therefore, greatly obscures the appearance which the acid brings out.

(3), Submerge the whole organ in a 5 per cent. aqueous solution of nitric acid, (B. P.) for about ten minutes, that is to say during the time the surgeon is cleaning out the axilla.

(4), Wash in plenty of running water for five minutes.

(5), Place in methylated spirit (undiluted) for two or three minutes.

(6), Examine the whole surface very carefully to ascertain (*a*), whether any part of the tumor is exposed on the surface, or (b), whether any locally disseminated cancer foci are exposed on the cut surface, or (*c*) whether breast tissue is exposed.

The effect of the above given method is to render all carcinomatous tissue and parenchyma dull and opaque white through coagulations of the albumen of the protoplasm of the cancer and epithelial cells. The fibrous tissue of the stroma is rendered gelatinous, translucent and homegenous in appearance and somewhat India-rubber-like in consistence. The fat is unaltered. If any dull opaque spots of carcinoma appear on the under surface of the breast, more tissue must be removed at the corresponding point in the wound. This point is easily determined if the breast has been marked as directed. After examining the surface of the organ it should be cut in thick slices which are to be treated in the same way; thus the various normal and pathological constituents of the mammæ can be readily and most satisfactorily studied. Cancer and parenchyma can be at once detected, if present, upon the cut surface and since the examination can be easily completed before the time for suturing the wound, this method affords the surgeon a valuable aid in ascertaining the limits of the disease, and of the organ.

DISCUSSION.

Dr. A. M. Vance: I would like to ask Dr. Roberts if he tried the method of detecting cancerous tissue in the case reported by him.

Dr. W. O. Roberts: I did not have an opportunity of trying it in this case. Mr. Chiene told me that his assistant was now using it in all his operations, and has great faith in it. I have a great deal of faith in Mr. Chiene and the first opportunity I have, shall try the method.

Dr. Wm. Bailey: I do not know that such a thing would be possible, but it occurs to me if some method could be devised whereby an observation or test could be made of the surface left after removal of the tumor to determine whether any cancerous structure remained—if this could be done in some way without injury to the patient—I think it would be a better thing.

Dr. T. P. Satterwhite: I believe the general rule, whether malignant or not, is to give full scope to all tumors, especially if the growth be of a suspicious character, an abundance of healthy tissue being taken away.

I remember a lady who, a few years ago, had a tumor about the size of a hickory nut in the breast, that gave her some discomfort and a little pain. I do not think her attention was called to it longer than a month before I removed it. I took the specimen to an eminent pathologist in the city, and asked him to make an examination and give me a positive opinion as to its character. He would not give me a positive opinion and I took it to a second pathologist who pronounced it carcinoma without any hesitancy, stating that it not only was cancer, but was an exceedingly malignant form. In removing that tumor I took out a quantity of healthy tissue, removing everything down to the muscle. The wound had no sooner healed than the growth returned; it was again removed, the tumor being no larger than a filbert; in a short time it returned again, showing that the last physician's opinion was correct.

I had a talk with Prudden, of New York, who is considered one of the best and most reliable microscopists in the country, with a view of testing as to whether or not all of the diseased or malignant structure had been removed at the time of operation, and he told me there was no possible way it could be done; that you might have a microscope there while operation was going on, to put a portion of the edges under observation, and yet it was an utter impossibility to tell. So I do not know how surgeons are to determine positively when they have removed all the diseased structure unless the method mentioned by Dr. Roberts is a reliable way.

Dr. Wm. Bailey: I can conceive how the work would be very difficult, because the cells cannot always be recognized under the microscope. It is only by the

arrangement of cells that carcinoma can be detected, and this may not be easily determined in all cases.

I rose to mention a case: Three or four years ago a woman, between forty-five and fifty years of age, came under my observation with a tumor in the breast that gave her some concern, some pain; tumor not much larger than the end of my thumb; it remained there with but very little growth for a year's time; in the meantime the woman became the subject of cancer of the rectum and died from it without further development of the cancer (which I believe it was) of the breast. The development of the growth in the breast was so slow and gave her so little concern that no operation was ever performed for its removal. The fact that the patient died of cancer of the rectum is confirmatory evidence that my diagnosis of cancer of the breast was correct.

Dr. J. M. Krim: I simply wish to mention the case of a woman who has been operated upon three times for cancer, and is still in existence. The first operation was twenty-three years ago when the left breast was removed; about two years afterward the right breast was removed, and I think it was a year later when the growth returned on the left side just below where the breast was excised; this time the tumor was allowed to reach about the size of an orange when it was carefully removed, and she has had no trouble since. Dr. Bayless, at the time, pronounced the structure malignant and evidently it must have been; however, it has been fifteen years since the last growth was removed and there is no evidence of a recurrence now.

Dr. W. O. Roberts: I have very little to say in closing. The only way is to continue to remove tissue until you fail to find evidence of carcinomatous structure. It strikes me that the method I have referred to is about as good as any. Of course it requires a man with some experience to carry on an examination during the time the operation is being performed, one, however, much less expert than would be required to use the microscope with frozen specimens. We endeavor, of course, in all cases to cut well beyond the diseased structures. There are some operators who make what is called a "cart-wheel incision," endeavoring to remove all diseased structures without any view whatever of approximating the surface afterward. There are some who remove all the tissues over the breast, go down and remove the greater part of the pectoral muscle, and then bring a flap up from behind to cover the breast—that is Halstead's method of operating. I think in all cases we should remove all suspicious tissue, and especially clean out the axilla—I believe this is of the most importance.

Dr. Wm. Cheatham presented "Paralysis of the Laryngeal Muscles, with Cases" as the subject for the regular essay. (See page 486).

DISCUSSION.

Dr. Wm. Bailey: One point—that is whether or not obstructions or difficulties of the larynx are not characterized by inspiratory dyspnœa instead of expiratory? I believe it is a fact that as a rule, as you go into a room where a patient is suffering with dyspnœa, you can locate the site of the trouble by observation of the dyspnœa. It is particularly characteristic that there is inspiratory trouble at the larynx, and expiratory trouble with other portions of the passage. We all know that a characteristic of emphysema is trouble in getting air out of the lung, difficulty in expiration. This is also true in obstructed respiration from other causes—if only one act is difficult, respiration is always slower than natural; if both acts are difficult then respiration is hurried. But if the obstruction is at the entrance of the larynx, or if it be emphysema, nature in a conservative manner prolongs the difficult act.

Dr. W. O. Roberts: I would like to ask Dr. Cheatham whether or not this tube his patient is wearing interferes with deglutition?

Dr. Cheatham: No, except for fluids.

SPASMODIC STRICTURE OF THE ŒSOPHAGUS.

Dr. A. M. Vance: I want to mention a case I saw once that has always puzzled me. I was called by Dr. Clements one night to see a little child three years old, that could not swallow. I introduced a stomach tube and put some milk into the child's stomach. I suggested that a trial be made with cocaine spray in the throat and soon discovered that the child

could swallow perfectly just after the cocaine was used. For a number of days each time the throat was sprayed with cocaine, the child could swallow with comparative ease. It soon irritated the throat so that it became sore. The child afterward died of pneumonia. I have often wondered whether there was some form of paralysis preventing the child from swallowing, or whether there was some neurotic condition which the cocaine relieved temporarily.

DISCUSSION.

DR. CHEATHAM: I have no doubt the case reported by Dr. Vance was spasmodic stricture, which was relieved by the cocaine.

Referring to Dr. Bailey's remarks: I have seen several cases of this kind where the trouble was in expiration, though, possibly as a rule the difficulty is in inspiration.

CASE OF BRAIN SYPHILIS.

DR. W. O. ROBERTS: I have a patient who is now forty-eight years of age. Twenty-five years ago he contracted syphilis. I saw him during the tertiary period of the disease, and he had very large and very extensive ulcerations of the soft structures of the extremities. I remember distinctly, one upon the elbow joint which involved the tendon of the triceps muscle. He had very large nodes on both tibia. He was under treatment with iodide of potassium, also some mercury for something over a year, and all the symptoms disappeared. He went to a distant city and remained for several years—probably a period of ten years. He returned suffering from asthma; it was so bad that he had great difficulty in breathing—could not go up steps or take any exertion without getting entirely out of breath. Under iodide of potassium these symptoms entirely disappeared. There was no valvular disease of the heart; no evidence of urinary or kidney disease. He suffered at the time he had asthma, from indigestion and he still complains of that trouble. A year ago he had most terrific headaches, and I thought at the time that they were possibly due to grippe. He was treated for that without benefit. Finally I put him on iodide of potassium which gave entire relief. After quitting the iodide for a period of six months, a node appeared on the forehead about as large as the first joint of my thumb. He was put back on iodide and this passed away and left a depression which can be easily seen at some little distance. He has had no headache for some time. A day or two after eating a hearty dinner, without any especial dyspeptic symptoms following at the time, he was taken with a well-marked attack of epilepsy, coming on by the jerking of one hand, finally shaking all over, then becoming unconscious, biting his tongue, frothing at the mouth and all the symptoms of well-marked epilepsy.

Upon inquiry I found that years ago while out West, he had a number of dizzy spells, but at no time lost consciousness, and within the last year he has had a number of these attacks, taking them to be simply vertigo from indigestion.

The question I want to ask is whether or not this epileptic attack is the result of brain syphilis; whether epilepsy occurs in a person of that age, except as a result of injury or structural disease of the brain.

DISCUSSION.

DR. W. P. SATTERWHITE: I should infer from his having had these severe symptoms of tertiary syphilis, that the present trouble is due to that cause.

DR. WM. BAILEY: There are several very interesting things in this connection, and I want to say this much in regard to the asthmatic attack—the relief by iodide of potassium of the asthma does not prove the syphilitic origin of the case, because iodide of potassium is the best known treatment for asthma. It will relieve more cases than almost anything else. I do not believe as a rule epilepsy occurs in a person of this age, but this man may have been subject of *petit mal* without knowing what it was.

I remember seeing a case with which Dr. Roberts is familiar, which I will mention in this connection: One evening after having eaten an enormous dinner, a man over fifty years of age had two attacks that were very much like epilepsy. He had no recurrence, and I thought the safety to him was by virtue of his age, and that perhaps it was brought on by disturbed circulation from over eating; he had been in bad health for months and had not at that time very fully recovered. This case goes to confirm my opinion that it is still very doubtful about the cure of syphilis. How are we to know when a

man is cured of this disease; when a man has gone practically for years and years without any new history, comes out again with decided manifestations of syphilis. We have by means of treatment with mercury and iodide of potassium brought it into subjection, so that for many years it may not manifest itself, but I have seen so many cases where after ten, fifteen and twenty years, symptoms develop again, that I have a little doubt whether we can be very sure about the absolute cure. I think I saw two sisters die neither of whom had any symptoms of syphilis for thirty years; both died apparently of brain syphilis. This disease is very difficult to eradicate, and we never know whether it has been done or not.

WESTERN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Annual Meeting: Kansas City, Missouri, December 27th, 1892.

[OFFICIAL REPORT]

Dr. Van Eman's paper. (See page 408.)

DISCUSSION.

DR. SHELDON: It seems to me, Mr. President, that the mere point of location of fecundation is not sufficient explanation for an adherent placenta. Whether it was at or near the mouth of the Fallopian tubes, or whether it was further within the body of the uterus, had there been no other factor, I think it would not have been sufficient to have produced the adherent condition. I take it that the class of adherent placentas to which the doctor has referred, is usually, if not always, caused by inflammation that has existed either as endometritis or as placentitis. One or both of those conditions must have taken place. This woman felt a pain in that locality during the whole of pregnancy. I think that is often, if not always, the case. There has been a low, sub-acute or chronic condition of inflammation, and new tissue has been formed connecting the placenta and the wall of the uterus. It has gone even further than that, and in some cases, where there has been extensive adhesions of the placenta, the muscular fibres have been often reproduced, extending from the muscular fibres of the womb into the placenta. As a rule, the new tissue is connective tissue, but we get another condition sometimes where the myoblasts or the fixed cells of muscles are reproduced, or reproduce themselves, until we get a muscular tissue extending from the wall of the uterus to the placenta.

Of course, we have many other causes for retained placenta, but I know of no other causes of adherent placenta, and the paper, it seems to me, should have been entitled, "Unusual Cause For Adherent Placenta," and not for retained placenta.

We may have retained placenta from irregular contraction. The circular fibres of the womb near the internal os or further up, make what is often called a "hour-glass" contraction. You may find it sometimes as the result of giving large doses of ergot. But we do not have an adherent placenta unless we have a formation of new tissue as the result of inflammatory action. I take it that the process which we call inflammation, in this condition as well as any other part of the body, is a physiological condition, and that it is an effort of Nature to repair a certain injury that has been done either to the placenta or to the endometrium, or to the walls of the uterus itself. There has been some injury done, either by some toxic germ or some traumatism, perhaps, or from some other cause, and Nature, in an effort to repair that injury, has formed new tissue and the new tissue forms the adherent condition that we find in these cases of retained placenta.

DR. LANGWORTHY: It seems to me that the gentleman in discussing the paper just read, and in giving the theory of inflammatory action as explaining the cause of retained placenta, has lost sight of the fact that the writer stated in his paper that this placenta was contained largely in the widely distended Fallopian tube. Now then, the gradual distension of this tube by the growth of the placenta would fully account for the pain which the patient experienced, leaving out any acute or sub-acute inflammation. It seems to me that a point in the paper has

been lost sight of, and that is, that it accounts for this retention by the hypothesis that the fixation took place in the tube instead of in the uterus in the usual manner; and the whole argument hinges upon the one theory that fixation takes place at the moment of fecundation. I once heard a scientist in discussing the theory of evolution, say he would like very much to believe that theory because it so nicely explained a great many things; but, unfortunately, there were some reasons why he could not believe it. Now whether there are any reasons why we cannot believe that fixation takes place at the moment of fecundation, I am not prepared to say; but the doctor, by this theory that fixation takes place at the moment of fecundation, very nicely explains the phenomena of abdominal pregnancy and, in the case of tubal pregnancy, that the placenta is adherent in the Fallopian tubes and various other phenomena in connection with this. I merely call attention to that point.

Dr. Shreves: I think Dr. Van Eman and Dr. Sheldon are both correct in that it is not doubted that attachments are caused by inflammatory action. The simple fact that the conception took place in the uterine end of the Fallopian tube, and the distention of that tube being gradual, would of itself create an inflammatory action sufficient to cause adhesion. I believe that Dr. Van Eman is correct, that there is the spot where the ovum and spermatozoa came in contact and that there the attachment is first formed. In the past five years I have had two cases similar except, that in one of them there was an hour-glass contraction with an attachment in a funnel-shape pouch at the uterine end of the Fallopian tube. I could pass my finger very readily into the tube and it was a perfect funnel-shape, and there was where the attachment was in both cases. One was simply a retention with a very slight attachment at that point, and in the other there was extensive adhesion coupled with an hour-glass contraction. At the removal of each placenta I was extremely careful to examine the opposite cornus of the uterus, and I found everything in a normal condition, but the complete funnel-shaped pouch in the right side of each case.

Dr. Lanphear: As a student of pathology, and not as an obstetrician, I beg to call attention to the fact that inflammation does not occur from simple irritation, from the presence of a fetus, or any other body. Inflammation is of itself infective in origin. There cannot be inflammation without an infective process going on. That is a fundamental principle of modern surgical pathology. Therefore the mere presence of the fetus in the Fallopian tube does not inflame and cannot excite inflammation. Where apparent inflammatory processes are present it is where rupture has occurred and where nature has attempted a repairative process, but in that process of repair, inflammation does not take any part unless there is infection from some outside source.

Dr. Sheldon: Allow me to ask what you mean by infection—that you can't have inflammation without infection?

Dr. Lanphear: I mean to say this, that inflammation never comes from simple irritation; that is, there must be infection from gonorrhœa, from sepsis, from something outside, or possibly, from the presence of destructive pus from the inside; but there is no such a thing as inflammation arising simply from the presence of the fetus, or anything else that is not implicated with the infective material, septic or otherwise.

Dr. Sheldon: It seems to me that I am not ready yet to accept the theory advanced by Dr. Lanphear, that we cannot have inflammation without infection. If I understand pathology correctly, the condition that we call inflammation and the condition that we denominate repair of tissue are indentical.

I take the position that, so far as we know, there was no infection in this case, but there was a condition of repair and formation of new tissue. I take this to be a pathological fact that each tissue reproduces itself and nothing else—reproduces itself or a similar substance histologically. Now, as I said before and as the doctor found here, there was new connective tissue that had formed between the endometrium and the placenta and that, of course, extended up into the tube; it matters not where it was, but that was the condition that he found. And this new tissue had been developed from connective tissue cells, but there is no indication that there had

been any infection there. Take, if you please, a simple incised wound or a simple contused wound, and perhaps that is what the doctor had here. He might have had traumatism; we don't know. But there was something that had injured the tissues there, and nature had set up an effort to repair that injury. We get the same thing when we have a wound; we get an increased hyperæmic condition; we have more or less swelling of the parts; we have effusion of the leucocytes and blood serum in the tissues that are to be repaired. Nature makes all this effort, and in this effort new tissue is produced from the existing fixed cells. Now, in subcutaneous incised and contused wounds we don't have any infection that we know of. I don't think it can be proven that we have, but we have a condition that we call inflammation, or a condition which I and others are pleased to call, a condition of repair. That noted surgeon of Philadelphia, Dr. Roberts, says that inflammation is a physiological condition, that it is an effort of nature to repair injured tissue. Those are not his words exactly but those are his sentiments. Senn says, in his work on surgical bacteriology, that inflammation is a physiological process, an effort that nature makes to repair injured tissue, etc. Almost identically the same words are used by those two authors; and nowhere, can I find a statement that it is necessary to have infection by some germ, or whatever it may be, in order to have inflammation.

Dr. Van Eman: The first objection that I hear, is that the title of the paper should read "adherent" and not "retained." I haven't any objection whatever to changing the title.

Now as to the cause; possibly there was inflammation there; possibly, on the other hand, nature found something was wrong and undertook to wall the thing in. That is theoretical.

The woman was delivered, and inside of twenty-four hours, in spite of every cleanliness, she has developed every evidence of septicæmia; there is constitutional disturbance and everything else. It may be she was infected by the doctor, and it may be she had infected material in the Fallopian tube for which the doctor was not responsible at all. If a man falls down in going home and gives his ankle a violent wrench and goes to bed and, if he goes to sleep at all, wakes up in the morning with it swollen the size of two or three ankles, there is certainly inflammation there, but whether it is from germs or not I don't know. Now when this placenta was retained, it hadn't anything whatever to do with inflammation. There was nothing in the paper about inflammation; I have not been discussing the question of inflammation and I do not propose to discuss it now. But I wish to say that during the second stage of labor, the voluntary muscles aided very little in the expulsion of the fœtus, that is in bringing it down into the vagina—and that was very largely caused from this placental adhesion acting as a splint to one side of the uterus, preventing the contractions and making them irregular. Now had this been simply an adherent placenta without any abnormal location of any portion of it, those contractions were certainly firm enough to have pulled it loose from the uterine wall, as is done in every case of delivery, whether it be normal or abnormal. It didn't do it simply because a large portion of the placenta laid out in the funnel shaped extremity of this tube, and the uterine walls were dilated by it and hadn't any power to contract and express. It was just simply held up there as if it had been tied, or occluded or set in there. Had this woman been so unfortunate as to have fixation of the ovum take place further out, we would have had the same funnel-shaped dilation of the tube but different results. Now it was simply funnel-shape here, but had no contractile power; even if the uterus did contract on it, it simply shut down. The moment I got my two fingers in there and worked around and detached it, my hand and the placenta were promptly expelled. It dosen't make any difference so far as this paper is concerned, whether the woman had inflammation or not.

As to the history of the case; I didn't wait upon her in her two previous labors, but I had known her more or less since her marriage. She came under my observation about the fourth month of her pregnancy; she had been to half a dozen doctors and some said she was pregnant and some said she was not. I decided she was and the results proved it. In five months more I delivered her—assisted in delivering her rather.

Now the reason why this placenta was

retained; it was simply grasped as you grasp a hand, and if it had not been that those contractions were exceedingly powerful—she was a very strong woman—if it had not been for those powerful contractions it would have been expelled very promptly. There is no resemblance between this case and the hour-glass contraction, except that possibly you might have an hour-glass contraction following. All I have to say is that in the hour-glass contraction, twenty-five years ago when I studied medicine I was instructed to give ergot; I wasn't even told not to give it. In primiparæ I was to give ergot; if I got tired, instead of putting on the forceps, I was to give ergot. And I want to say right here that the man that calls himself a doctor and has so little judgment that he would put on the forceps to get away, or put on the forceps in the condition described by Dr. Price, isn't fit to look inside of a lying-in room, much less to take charge of a patient. After awhile I found that ergot wasn't to be given indiscriminately; and I had more hour-glass contractions when I gave ergot than I have since without giving ergot. But the man who gives ergot without reference to the stage of labor because somebody else gives ergot, and doesn't make any use of his brains, will have plenty of hour-glass contractions and plenty of retained placenta, whether they are adherent or not.

Pregnancy and Ovarian Tumor.

Dr. Wm. Gardner (*Montreal Medical Journal*) says:

The association of pregnancy and ovarian tumor, if left to nature, is fraught with danger to the woman, whether the termination be premature, or at full term. When left to nature, abortion or premature labor may occur, in either case with frequently fatal results to the mother.

When the case proceeds to labor at full term, the result to the mother may be rupture or such other injury to the tumor that fatal peritonitis carries her off.

Tapping of the tumor, while it may temporarily relieve tension, is by no means free from danger by injury to the uterus, or otherwise, and it does not cure the patient.

Ovariotomy with modern precautions is nearly as safe as in the non-gravid condition of the uterus, while the woman is at once cured of a disease which must ultimately demand operation.

The second case here related shows that serious complications such as torsion of the pedicle and consequent peritonitis with adhesions, necessitating the use of the drainage tube for so long a period as five days, does not necessarily lead to abortion.

Ovariotomy in the present status of surgery, in the great majority of cases, must be the only proper treatment, and is often urgently demanded to relieve tension.

The indication for the operation in the case of small abdominal tumors is even more urgent, because of their great liability to torsion of the pedicle; and in the case of the pelvic tumors, by reason of the almost certain rupture or necrosis from compression during labor.

Mark Twain, says an exchange, was at one time director of an accident insurance company, and being called upon at an entertainment in London to make a speech, introduced the following allusions in his remarks: "Certainly there is no nobler field for human effort than the insurance line of business—especially accident insurance. Ever since I have been a director in an accident insurance company I have felt that I am a better man. Life has seemed more precious. Accidents have assumed a kinder aspect. Distressing special providences have lost half their horror. I look upon a cripple now with affectionate interest—as an advertisement. I do not seem to care for poetry any more. I do not care for politics—even agriculture does not excite me. But to me, now, there is a charm about a railway collision that is unspeakable.

There is nothing more beneficent than accident insurance. I have seen an entire family lifted out of poverty and into affluence by a simple boon of a broken leg. I have had people come to me on crutches, with tears in their eyes, to bless this beneficent institution. In all my experience in life, I have seen nothing so seraphic as the look that comes into a freshly mutilated man's face when he feels in his vest pocket with his remaining hand and finds his accident ticket all right. And I have seen nothing so sad as the look that came into another splintered customer's face when he couldn't collect on a wooden leg.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 1ST, 1893.

EDITORIAL.

ANÆSTHESIA.

The New York daily papers, of the 26th of March, contained a statement over the names of the attending surgeons, and made, it is said at the request of the family and friends of Col. Elliot F. Shepard, concerning the death of the latter under ether. The statement is substantially as follows: On Friday afternoon, March 24th, ether was administered to Mr. Shepard with a view of exploring the bladder for stone and, if practicable, removal of the calculus. The statement is that ether was begun at 12.45 P. M. and that for a few moments he inhaled "uncommonly well, his breathing being full and free." Afterwards (time not stated) "his color changed somewhat and it was apparent that he was nauseated. In another moment he vomited. After this his color was better, but as his respirations were not satisfactory, nor his pulse, the further administration of the anæsthetic was discontinued. As yet not enough ether had been given to admit of proceeding with the proposed operation." . . . . ."The breathing continuing very labored, an examination was made of the larynx to determine whether possibly some article of food had lodged in it, but such proved not to be the case."

"The patient's condition was now so alarming as to call for extreme measures, and in hope that the symptoms might be due to the presence in the wind-pipe of vomited material accidentally inhaled, the operation of tracheotomy . . . . . was performed. No foreign material of any kind was found and we *even passed a rubber tube down the wind-pipe and into the bronchial tubes, making use of a powerful aspirating syringe* without discovering the presence of anything but bloody mucous."

Oxygen was used "and under its influence the patient slightly revived." "Artificial respiration, and every other means which might possibly give relief, was resorted to." "From this time on his breathing became even more embarrassed, but still artificial respiration was contin-

uously kept up although the pulse became steadily more feeble."

"He sank rapidly into unconsciousness, and, in spite of all efforts, died at ten minutes after 4 o'clock. In our opinion Col. Shepard died of sudden œdema and congestion of the lungs following the administration of ether, but, primarily, due to some cause unknown to us."

(Signed) JAMES W. MCLANE,
CHAS. MCBURNEY, M. D.

This statement, while prepared for the public press and not for the profession probably covers the matter sufficiently to justify comment. The names attached to the statement are sufficient guarantee of the skill and ability that would be applied to avert such a calamity by every known means that could be made available. The statement gives the impression that death was due to ether, certainly as the exciting cause. Can this death be justly ascribed to ether? The diagnosis of œdema of the lungs was made apparently on physical examination alone; no *post-mortem* was made and, in the absence of any technical description of the case, we are left in doubt as to the true cause of death.

It would certainly be most extraordinary for œdema or congestion of such proportions and rapid fatality, to result from the inhalation of ether given over so short a period of time that the patient was not sufficiently anæsthetized to permit of starting the operation. Bronchorrhœa is an ordinary complication, but in such proportions as to prove fatal as in this case is unheard of. To us it would seem more probable that an apoplexy had taken place in the brain. And before charging the death to the account of ether, it would be well to know just how the ether was administered.

This unfortunate occurrance serves to strongly emphasize the fact that anæsthesia is *never without danger.*

Mountains of words have recently been piled up concerning anæsthetics and their physiological actions. The researches and the discussions of the Hyderabad Commission have been published throughout the world, and the ultimate result appears to be an irreconcilable conflict as to whether chloroform kills by paralyzing the heart or the respiratory centers first. Ether as an anæsthetic was practically ignored.

But the every day practitioner does not care so much to learn how to kill his patients by anæsthetics, as he does glow to extend to them the blessings of necessary unconsciousness with the greatest security to their lives and welfare. The ideal anæsthetic—that which will suspend all functions but life itself; that, without any disagreeable coincidences or consequences, will allow the patient to come out from its influence in a better condition than before going under; that no organic disease of brain, heart, kidney or lungs will offer contra-indication to its use; that will act instantaneously and alike in all classes and conditions—the ideal anæsthetic has not yet been discovered, and probably never will be until time has passed into the millenium.

In the meanwhile, it behooves us to use the agents at our command with discretion and pains-taking care. Experience both as an anæsthetizer and as an operator has lead to the following general conclusions: Everything taken into consideration, ether is the desirable anæsthetic for use in general work. The principal objection urged against it, *i. e*, its irritant action upon the kidney and consequent contra-indication where kidney disease exists, is much more apparent than real. Certainly we would prefer to take the risk of the effects of ether on the kidney rather than to take the chances of using chloroform with its attendant and multiform dangers.

The successful use of ether depends on the anæsthetizer and the quality of the ether used. Possibly many of the

lives that have been lost under chloroform, and probably most of those lost under ether, might have been saved had the fact being recognized that the anæsthetizer is a factor of importance not inferior to the operator himself. If it were more generally realized that it is the *anæsthetizer* who, in ninety-nine cases out of a hundred, holds the life of the patient absolutely in his hands, and that with *him* rests the present issue of life or death, the custom of entrusting this duty to the hands of the least experienced and youngest man available would be relegated to the limbo of the relief of barbarism, and the mortality lists of operators would show a marked decrease in death from "shock." It is not often the operator loses a case "*on the table.*" Not infrequently does he lose his patient from "surgical shock," which might well be called "*drowning by anæsthetics.*"

The anæsthetizer must be pre-eminently a man of common sense. He should appreciate his responsibility, and if he does this he will know, see or hear nothing but the condition of the patient whose life ebbs or flows at his will. He has absolutely no business to know what is taking place apart from his own duties. He must possess confidence in himself, and be able to inspire his patient. Almost always he can gain a control over the will of the patient that will very materially aid in the successful performance of his office. His responsibility begins with his first introduction to the patient and does not end until the patient has safely recovered consciousness.

Of importance also is the *quality* of the drug used. Experience has shown that ether kept for a long time in a drug store, exposed to light or not hermetically sealed, will deteriorate. If it is not deterioration it is adulteration. Sulphuric ether, thoroughly washed and put up in sealed cans, is said to keep indefinitely. One accustomed to the use of ether can readily detect by the effect upon himself and the rapidity of evaporation, whether the drug is effective or not. Sulphuric ether unless thoroughly washed is potent for producing the distressing after effects of ether sickness.

The *quantity* of the drug used is immaterial. It is the effect upon the patient that is essential.

Patients who suffer from bronchorrhea are most apt to have the after sickness. Alcoholics are less susceptible to the effects of ether and more difficult to manage than are those free from the influence of alcohol. Ether acts more quickly and produces less ether sickness in patients who have nothing in the stomach, and whose bowel has been thoroughly emptied previous to receiving the anæsthetic. Abstinence from food or drink for twenty-four or more hours after anæsthesia will prevent much of the after sickness. Where retching is uncontrolable the use of small quantities of hot water to afford the stomach something to dispose of, will generally stop the distressing condition.

Strychnia administered hypodermatically is the best and safest stimulant where profound depression requires its use.

Of the greatest importance, and the end to be unceasingly sought for by every administrator of anæsthetics, is that condition, the golden mean between consciousness on the one hand and coma on the other. No one indication holds good for all cases. Muscular reflexes are snares for the unwary. The sensativeness of the conjunctiva is absolutely valueless. An experienced anæsthetizer can often estimate the degree of unconsciousness by the reactions of the pupils to light. But it is not at all a safe criterion.

But there is one indication that applies to the vast majority of patients under anæsthesia, and is the most reliable of all signs for estimating the degree

of the condition: If a patient has passed into the third stage of anæsthesia—the stage of the abolition of all voluntary muscular effort, the reflexes inhibited and complete relaxation obtaining—now, if the ether be withdrawn for a short time and then readministered, the patient will show the signs of irritation in the throat by the *motions of swallowing* and, if the ether has been withdrawn too long, by choking. This point, *where the addition of a little fresh ether will cause these efforts at swallowing*, is the land mark by which to gauge the depth of anæsthesia.

It is the line where the second merges into the third stage of unconsciousness. Sensation is abolished, muscular relaxation is established and all the senses are held in abeyance. The complete withdrawal of ether will allow speedy reaction; the addition of fresh ether will deepen the unconsciousness. A safe rule, therefore, is to try the effects of a little fresh ether frequently, *and if it produces no signs of irritation in the throat, withdraw it.* The anæsthesia is sufficient. If, however, fresh ether *produces the evidences of irritation, continue the administration until fresh ether will not cause the signs.* If this is not done the patient will continue to regain consciousness, with the undesirable effects of muscular resistance, etc.

Never forget that many patients will pass through the first and second stages with considerable resistance and excitement, and, reaching the third stage, will plunge into a coma so profound as to excite alarm.

Anæsthesia should always be administered with due regard to personal idiosyncracies of the patient. Always with gentleness and encouragement to the patient; never rudely or suddenly. The mental impression has much to do with the ultimate results.

In certain major operations, for instance an hysterectomy, where the removal of a member entails profound shock, the shock may be very much lessened by deepening the coma at the instant of removal.

Simplicity in every detail; exclusive devotion to his duty on the part of the etherizer; a constant realization that his actual responsibility is equal if not superior to that of his principal, and the guidance of all action by hard common sense are elements necessary to qualify one for success as an anæsthetizer. Unfortunately comparatively few physicians are capable of safely administering an anæsthetic, and this, too, without any excuse whatsoever.

As medical men realize the vital responsibility attaching to this office and adjust themselves accordingly, the number of deaths alleged to be due to anæsthetics including the treacherous chloroform, will very markedly diminish, and those deaths from the water-logging of the system yclept *shock* will exist only in the records of the past.

---

*Dr. V. R. Hacker reports that in the clinic of Billroth during the last ten years there were treated in all 41,366 patients. Among these were 270 suffering from diseases of the œsophagus. Of these, 131 cases (114 males, 17 females) from carcinoma, 47 cases of stricture due to cauterants, chiefly lye (18 males and 29 females.) The results of the cases of cauterization were as follows: One-third at least died from the direct poisonous results of cauterants taken with suicidal intent. Those cases following the use of lye one-fourth proved fatal, and more than one-half died from sulphuric acid poisoning. Those who recovered from the first effects of the lye poisoning more than 50 per cent. suffered from grave stricture, the remainder having milder forms of stricture. More than one-third of those who survived the sulphuric acid poisoning suffered from grave strictures. —*Schmidt's Jahrbucher*, Bd. 237, No. 1.

TRANSLATIONS.

AN OPERATIVE PROCEDURE APPLICABLE TO LARGE PUS TUBES CLOSELY ADHERENT TO THE UTERUS.†

Chaput (*Jour. de Méd. de Paris*, Jan. 15, 1893) remarks that the treatment of pelvic suppuration remains the order of the day. Some, including Péan and Segond, persist in performing vaginal hysterectomy in preference to laparotomy for all cases of bilateral suppuration; others, represented by Pozzi, le Denter, Terrillon, Championnière, Terrier, etc., claim that hysterectomy should only exceptionally be performed, reserving all their sympathies for laparotomy. Chaput classes himself with the latter writers, and only undertakes hysterectomy when he recognizes, after opening the abdomen, that ablation by the other method is absolutely impossible. He also prefers hysterectomy when there are purulent fistulæ opening into the bladder, vagina or rectum. He regards hysterectomy as an operation full of dangers and disagreeable surprises; patients are often lost by hemorrhages and, moreover, septicæmia is the principal cause of death, and it appears more frequently than in laparotomy. Hysterectomy also exposes the small intestines, the pelvic colon, the rectum and, at times, the cecum to the danger of being wounded; the uterus, and especially the bladder, are often perforated. Finally vaginal hysterectomy leaves in the abdomen the entire sacs, open or intact, and it must be remembered that the subsequent treatment of this operation is difficult and delicate. Without much danger of septicæmia, laparotomy does not expose the viscera to the danger of wounds; it usually permits of complete ablation of the disease and the after-treatment is particularly simple.

Chaput calls attention to a serious complication in which the tubes adhere strongly to the uterus, and cannot be separated without the risk of a hemorrhage very difficult to control. In a case of this kind he follows a technique which he deems of sufficient interest to report in detail. The history of a case of this class is as follows: A woman, 38 years old, menstruated at sixteen normally. At 23, she was delivered of a child without any attendant complications. She nursed her child for one year although the menses returned normally at the end of three months. At 26, she had a miscarriage from which she appeared to recover rapidly and completely. There were no clear proofs of gonorrhœa. She commenced to suffer from uterine disease in July, 1892; at that time she was seized with violent pains in the right iliac fossa, propagated to the thigh. From this time she suffered constantly in the abdomen and thighs; her menses lasted fifteen days and were abundant and painful. During the fifteen days that followed there existed a very abundant leucorrhœa. On her entrance into the hospital on September 26, 1892, the patient was anæmic but not emaciated, and her general condition remained satisfactory. The abdomen was voluminous. On abdominal palpation a median tumor was noted extending nearly to the umbilicus, the surface of which was smooth and regular, the consistence very hard and the dullness absolute. There was no ascites. To the touch the cervix was found to be very voluminous, hard, regular; the orifice was a little patulous. The neck, very much contracted, was continuous with a hard voluminous tumor, filling the cul-de-sac, and which appeared to occupy the body of the uterus and to lose itself in the mass observed by abdominal palpatation. The mobility of the tumor was almost nil. Impulses communicated to the abdominal mass were transmitted feebly, but clearly to the uterine cervix. Chaput inclined to the diagnosis of salpingitis rather than fibroma, basing his views especially upon the considerable fixity of the tumor which did not appear immobilized by its volume, and because there were no symptoms of vesical or rectal compression. The urine was normal, cystitis did not exist, nor frequent micturition, nor was constipation present.

He decided to perform a laparotomy in preference to a vaginal hysterectomy, (1), because of the obscurity of the diagnosis; (2), because in case it were a fibroma, there

†Translated for The Medical and Surgical Reporter, by W. A. N. Dorland, M. D.

was a good chance of being able to perform castration, a simple, benign, and efficacious operation. The operation was performed and an enormous collection of pus found in the tube. This was aspirated with Potain's apparatus. It was very fetid, grumous, and amounted to about 250 grammes. A large quantity remained in the sac. During the process of enucleation of this sac, it ruptured into the pelvis; sponges, however, were placed to prevent inundation of the large peritoneal cavity. The sac being very sessile the membrane pedicle was divided into two portions, after which the sac was drawn out. It was then found that the tumor was strongly adherent to the pelvic colon, the adhesions being so intimate that they had to be severed by scissors. The sac was also adherent to the right side of the uterus and decortication left a large bleeding surface which rendered supra-vaginal amputation indispensable.

It was decided therefore, to do this, but after vertical section of the uterus through its entire length. This section presents the following advantages: the pedicle of the uterus is less voluminous, being divided, therefore more easy to treat. Moreover, the medium section being prolonged below, the vagina is opened and it becomes easy to establish an abdomino-vaginal drainage the employment of which is formally indicated on account of the issue of pus in the peritoneum. The total median section is followed by only an insignificant exudation of blood.

In the case quoted, to the left there existed a suppurating salpingitis up, the broad ligament cut between of small volume. This was drawn two forceps and upon the left uterine pedicle was placed a gum elastic ligature. The membranous pedicles were ligated with silk, the pelvic cavity cleansed with sponges soaked in carbolic acid of 21–20–0. Finally an abdomino-vaginal drainage was established. A smaller tube of large caliber, twenty cm. long, furnished with holes in its lower half only, was introduced by the abdomen down to the vagina, the latter having been disinfected before the operation. Two hemostatic forceps seize the lower orifice of the tube in the vagina without obliterating it. The upper extremity of the tube is traversed close to the abdominal wall by a sterilized English pin, then protected by a dressing of iodoformized cotton. A little iodoform gauze is rolled around the forceps at the entrance of the vagina. Every six hours the abdominal dressing is removed and the tube irrigated with boiled water which escapes readily by the vagina. The tube is removed at the end of ten days and from this time a daily vaginal injection of bichloride is given. At the end of a month the elastic ligature comes away per vaginum, and the patient is completely cured.

By means of the abdomino-vaginal drainage, iodoform poisoning and stagnation are avoided. It may be mentioned here that the tube determines intestinal adhesions which constitute a sort of diaphragm which protects the peritoneal cavity. Chaput gives this operation the name of *Supra-vaginal amputation, with total median section and abdomino-vaginal drainage.*

Muscular Ruptures.†

Duplay (*La Méd. Mod.*, February 15) describes injuries of the muscles, the results of violent muscular effort, as of three kinds, viz.:—1, Luxation of the muscle; 2, Hernia through the aponeurosis; 3, Rupture of the muscle.

Luxation is a rather rare condition, and, in fact, is denied by some. Hernia consists in a tear of the aponeurosis with a protrusion of the fleshy substance of the muscle through the tear. This lesion is especially seen in the adduction of the thigh and gives rise to symptoms almost pathognomonic; there is a relaxation of the aponeurosis through which the muscle forms a hernial protrusion during contraction. There is also a change in the volume of the tumor according as to whether the muscle is in the state of contraction or relaxation.

Rupture of the muscle may be complete or partial. *Complete* rupture takes place most frequently at the union of the muscular and tendinous fibres, but, at times, it may occur in the middle of the muscle, especially in the biceps muscle. In *partial* rupture only certain bundles are involved; the separation between the two ends may be felt, especially at the upper end. If the muscle contracts the upper end protrudes considerably, while below there is a marked loss of substance

†Translated for The Medical and Surgical Reporter by W. A. N. Dorland, M. D.

noticed between the two divided extremities. These symptoms are difficult to observe when it is a deep muscle that is involved. On the other hand the diagnosis may be notably obscured by the production of an enormous blood effusion. Richardson has observed an effusion of at least a litre of blood. It might be conceived that the existence of an effusion of this kind might markedly hinder the correct diagnosis of rupture of a muscle. But in short this effusion itself, if it does not exceed certain limits forms part of the symptomatology. It always gives rise to an intra-muscular hematoma, which aids in the diagnosis. Finally there is a third variety. It is a rupture still more partial, we might say, a fibrillar rupture, in which the muscular rupture compared to the tear of the vessels, plays but a secondary role. The condition is nearly exclusively marked by the hematoma. There has indeed been a muscular tear, but this tear is fibrillar, but slightly extended, and the hematoma constitutes the essential element. If the hematoma is cured the muscular rupture will not give rise to any trouble.

In every case, in order to complete the diagnosis, it is necessary to ascertain whether, independently of traumatism, there exist other conditions that might favor the tear. At times there are found some very important predisposing causes, especially is this the case in individuals affected with grave infectious diseases. Then, under the influence of the muscular alterations noted by Hayem (granular and fatty degeneration), a very slight muscular contraction, such as is caused by the patient turning in bed, may give rise to a muscular tear. The great rectus of the abdomen on the right side is exposed particularly in this case; sometimes, as in typhoid patients, a tear of both recti may be observed. In these cases the hematoma nearly always ends in suppuration; whence a special variety of sub-aponeurotic abscess of the abdominal cavity may give rise to strange errors in diagnosis. In healthy individuals such is not the course, and suppuration is quite exceptional. Usually affairs rapidly change for the better. When the tear is not very extensive, so as to cause non-union, cure is usually very rapid. On the contrary, in infected individuals, suppuration frequently results.

There remains to be mentioned a last and very interesting termination; this is the persistence of the hematoma in the form of a tumor, generally small. It is a solid tumor; at times as hard as wood. If the initial traumatism is not known the most singular errors of diagnosis with every possible and imaginable tumor may be made. It is necessary, therefore, to think always of the possibility of these tumors. They may appear after a simple muscular contusion. It is necessary also to note especially in the lower limb a possible grave sequel. The muscular tear occurring in the lower limb is known, vulgarly, by the name of "*coup de fouet.*" If varices, even latent, exist there may be produced, under the influence of the tear of the vessels, a veinous thrombosis. If then a violent form of treatment be instituted, massage for example, embolism, even fatal, may be produced.

Treatment of incomplete or partial rupture with the formation of an hematoma. The first indication is absolute rest of the muscle. If possible it should be relaxed completely. Local applications: emollients at first (laudanum poultices, etc.) A little later, if the blood is slow in being absorbed, some revulsives may be given with a little compression. For the lower limb avoid massage for fear of embolism.

A Report of all the Laparotomies Performed in the Clinic of Prof. Billroth during the last Twenty-five Years.*

Hansy and Dr. E. Knauer report 969 operations, not including those operations for hernia, extirpation of tumors of the abdominal wall, opening of the peritoneum, extirpation of the uterus *per vagina*—or operations on the rectum or bladder.

Cases	Recov.	Deaths	Total
Ovariotomies	340	127	467

Further Contributions to the Studies of Operation for the Removal of Goitre.*

According to Dr. Ar. Eiselsberg, of Vienna, of the 52 operations for the *Total Extirpation of Goitre* at the Clinic of Billroth until July, 1892, 3 died suddenly (collapse, sepsis and entrance of air). The further results of the total extirpation were as follows: 12 suffered from tetanus, 11 from cachexia strumipriva, 10 made uninterrupted recovery (3 of these had no return; in 7 there was a return). The cachexia in one remained the same after as before the operation, and in 15 the results were either not known, or the time since the operation for reporting was too short. The author feels, therefore, that he can present the results, immediate and remote following this operation in 70 per cent. of the cases seen. Among the cases operated, there are 6 which do not correspond with our present views regarding the function of the thyroid gland. These are the 3 cases of cachexia with return of goitre, and 3 cases in which there is no return; all of whom remained well. He, especially, speaks of 12 cases done since July, 1885 to 1889, in which *more than four-fifths* of the *goitre was extirpated.* Of these, five died (1 from tetanus, 4 from collapse, sepsis and pneumonia); 4 patients subsequently suffered from tetanus but recovered later, much improved; 3 recovered entirely and remained so. *Partial extirpation in which at least one-fourth of the goitre was left,* was done 47 times with 42 recoveries. Mild symptoms of tetanus were noticed but in 1 case following the operation. *Enucleation of the goitrous nodule* was performed in 40 cases with 38 recoveries. *Ligation of the four arteries*, according to Wölfler, was performed 7 times for large diffuse struma, resulting in each case in contraction of the growth. In 3 cases the result was a very desirable one. Of particular interest is the report of one case in which acute suppuration of the thyroid gland was followed by tetanus, which had previously become colloid in nature and later took on sarcomatous degeneration. The author concludes from the results of these various operations that those cases in which a certain portion of the gland was allowed to remain—to continue to functional activity—it became the means of controlling the graver complications.

*Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

Contributions to the Studies of Carcinoma of the Thyroid Gland.*

Dr. Hinterstoissen, the author, has based his studies upon fifty cases of carcinoma of the thyroid observed by him, during the past years in the Pathological Institute of Vienna. Twenty-eight occurred among men, and twenty-two among women. In the majority of cases the tumors presented a large circumference. In several cases the primary infection was almost unrecognized in contrast to the metastatic swellings in distant organs. The capsule of the thyroid was usually found, even in large tumors, to be intact. Particularly interesting was the relation which this tumor bore to the neighboring organs, such as the larynx, œsophagus, the large blood vessels and the nerves. The integument was rarely found to be adherent. In contradistinction to the carcinoma of the other organs, in which the infection follows the lymph channels, the thyroid variety extends preferably along the blood channels. The implication and induration of larger venous trunks near this tumor was found in eleven cases. In thirty-five cases secondary deposits were found in the lymph glands; in twenty-nine cases metastatic centers were found in the lungs. In isolated cases metastatics were found in the liver, heart, kidneys, and brain substances, and in ten cases metastatics were found in the bony system.

Histologically the author divides it into three classes; first, the *adeno-carcinoma*, which he subdivides into two, (*a*) adeno-carcinoma with partial or entire follicular construction and with colloid formation; (*b*) the cylindrical cell, adeno-carcinoma.

Second, the *medullary carcinoma* which is the most frequent.

Third, the *fibrous carcinoma.*

In his closing remarks he speaks of the diagnosis as being exceedingly difficult in the earlier stages. Since a benign growth frequently takes on malignant degeneration, and the exact time of this change is impossible for any physician to know. The operative results have up to the present time been very unfavorable.—(*Schmidt's Jahrbucher*, Band 237, No. 1.)

*Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

ABSTRACTS.

THE SURGICAL THERAPY OF RECTAL CANCER.

Manley, of New York, gives (*Merk's Med. Bulletin*, Feb., 1893), the comparative values of the different operations for rectal cancer—tentative and radical—gathered from the published records of various surgeons.

In the London Hospital, from 1872 to 1880, thirteen colotomies for cancer were performed, with nine deaths. During the same time, says Cripps,* 26 such operations were performed at Guy's Hospital with 11 deaths—a mortality of about 42 per cent. It does not appear whether this was an operative mortality, or whether those were simply classified under "mortality," who died before leaving the hospital. Allingham gives 27 colotomies with a mortality of 11 per cent.

Cripp, says of colotomy that in some it affords relief from pain, while in others it has failed to do any good. Of course, in *complete* intestinal obstruction, a colotomy *must* be done.

Of later years, in France, Pinault, Velpeau, Récamier, Massé, Chassaignac, Maisonneuve, and in Germany, Freinonze, Nussbaum and Schuh, revived the operation of rectal resection for cancer, and in England, Paget, Jordan, Holt, Allingham, Gray and Holmes gave it their support.

In Cripps's Jacksonian essay on 36 recorded cases of extirpation *per-rectum*, defæcation became normal in 23; could not be retained when fluid in six and incontinence continued in only seven.

In all cases it appears that incontinence is the rule immediately after operation, but as the wound heals control is regained. Retention of the fæces, however, *is possible* in many instances even after the entire sphincter has been cut away.

In another table of Cripps', we find, of 66 recorded cases of extirpation: 44 recovered and 11 died—a mortality of 17 per cent.

Préchaud's tables,† made up from his own cases and the records of several other operators, give 149 observations on rectal cancer extirpations, of which there were 103 operative cures (69.13 per cent).

Immediate relapse in			3.
Doubtful results in			7.
Operative Deaths in			36.
69 relapsed	after		1 year.
15	"	"	2 years.
2	"	"	3 "
5	"	"	4 "
5	"	"	5 "

Hence, from the above, we must assume that, five years after operation, none but six could be accounted for,—or about 4 *per cent.* of all.

Charron gives us a table of results in 139 cases of colotomy(*). Of these,—

8 were missing and could not be accounted for.
54 died within 2 months.
65 lived from 2 months to one year.
5 lived from 12 months to 18 months.
3 lived from 1 year to 2 years.
6 lived 3 years or more.

It would appear from the above table that, in the results as far as prolongation of life is concerned, there is little difference ultimately.

It does not appear from these tables whether those who died, succumbed through a *local* recurrence of the malady, or as the result of a generalization or metastasis.

It is a matter of common observation that, when local, superficial epithelial growths are completely swept away by caustics or the knife, the disease most commonly recurs *rather in the internal viscera* than at its original site.

THE QUESTION, THEN, TO DETERMINE,

in a given case of cancer, is *not*—"what operation will eradicate the malady"; for *that* is clearly quite out of the question;—but rather,—"which will afford a temporary cure, and give the patient the greatest amount of *mental quiet* and bodily comfort; so that, when the end comes, it may be painless"; as we know is commonly the case when death is due to cancer of the internal organs.

On the main points which the question involves, modern surgery has made possible a quite general accord of opinion among operators.

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF OBSTETRICS FOR MARCH.

Dr. Jacob Rosenthal, of Dresden, contributes a paper on

An Operation for the Cure of Vesico-Cervical Fistula by the Sectio Alta.

The operation was devised by Trendelenberg for the relief of those cases of vesico-cervical, vesico-uterine and certain vesico-vaginal fistulæ in which, owing to the relations of the parts, the ordinary operation cannot be done; and is described as follows: "An extra-peritoneal suprapubic cystotomy is done, and after the bladder is opened the edges of the fistula are freshened and sewed; the bladder is then sewed up, leaving a small space for drainage; the abdominal incision is but partly closed, and the prevesical space tamponed with iodoform gauze and drained." In the case reported the patient, a primapara, complained after getting up that she was unable to hold her water. On examination the urine appeared to come from a slit-like opening between the bladder and the cervix high up in the vaginal wall on the right side. The anterior wall of the cervix had also disappeared and presented a funnel-shaped depression. It was impossible, owing to old and extensive adhesions, to operate *per vaginam*. The operation was performed by Prof. Leopold. The bladder was opened and found to contain a small soft stone which was removed. On further examination it was found that the fistula was high up on the right side of the bladder, opposite the descending ramus of the pubis, and that it communicated at this point not only with the uterus but also with the pubic joint by means of an irregular fistulous tract from which pus was oozing. An effort to freshen the edges of the fistula was found impracticable as the tissues had become too dense and adherent to the pelvis and there was little chance that the edges would unite. The urethra and ureters being beneath the fistula, a new bladder of reduced size was constructed by making a flap from the anterior wall of the bladder and another from the posterior wall, beginning beneath the fistula and approximating the two. The fistula was thus left outside the new bladder and was closed with catgut, an iodoform drain being introduced into the uterus. On exploring the fistulous tract leading to the pubic joint, the cartilage was found destroyed and the bones carious. The joint and fistulous tract were curetted. The patient made a good recovery. The literature of the subject is reviewed by the reporter and the paper is illustrated with cuts showing the condition of the bladder and the steps of the operation.

Dr. Paul F. Munde reports

Seven Unusual Cases of Congenital Malformation of the Female Genital Organs.

After discussing the subject of malformation of the female genital organs the author reports the following cases:

I. Imperforate vagina; rudimentary uterus; absence of ovaries. An artificial vagina was made in the hope that the uterus and ovaries might be stimulated to a more natural growth. On reaching the rudimentary uterus in the dissection a discharge of thick mucous took place. The small uterus was about one inch long. The edges of the external os were stitched to the margin of the newly formed vagina and the whole cavity packed with iodoform gauze. No ovaries could be detected.

II. Perfect female habitus; normal genitals and vagina; rudimentary uterus; absence of ovaries.

III. Perfect vagina; absence of uterus and ovaries; normal female habitus. In these last two cases there was no relief to be offered.

IV. Double uterus and vagina; congenital closure of the right half; hematometra and hematocolpos dextra lateralis. The septum between the two halves of the uterus and vagina was excised from vulva to fundus. It proved very thick and vascular, and numerous catgut ligatures were required to stop the bleeding. The patient recovered fully.

V. Double uterus and vagina; normal ovaries; dysmenorrhœa. This patient had been advised to have the ovaries removed on account of the severe dysmenorrhœa. The whole septum was excised from vulva to fundus resulting in the cure of the dysmenorrhœa. Dr. Munde does not explain the relief from pain in this case.

VI. Double uterus; pregnancy in the left half mistaken for extra-uterine. Laparotomy was performed under the impression that an extra-uterine pregnancy existed, or an interstitial pregnancy in the right horn. In order to reduce the size of the tumor as much as possible, so as to bring it out of the small incision, the amnionic fluid was aspirated. The sound had previously been passed to a depth of three inches; but on requesting the assistant to again pass it, to the operator's surprise it entered to a depth of five and one half inches and was plainly visible through the uterine wall. On withdrawing the sound and on entering it on the left it only passed to the depth of three inches, proving the case one of double uterus. The patient aborted twelve hours later and made an uneventful recovery. "It would be well to consider the possibility of making this mistake in cases of doubtful pregnancy, particularly in those where the fetus is claimed to have been expelled through a dilated uterotubal opening into the uterine cavity and delivered as in ordinary abortion."

VII. Double uterus and double vagina; right half parous and containing fibroid, left half rudimentary. The patient had had two children. A fleshy fold divided the upper half of the vagina and had probably originally extended down to the vulva but had been torn away in one of the labors.

The paper is illustrated with cuts showing the conditions existing in each of the cases reported.

Dr. L. S. McMurtry, in an able paper on

The Essential Question of Drainage in Pelvic Surgery

represents fully the views of those surgeons who are accustomed to use the drainage tube in their pelvic work. The objections to its use are also discussed and answered. After reviewing the principles underlying the use of the drainage tube and showing that incision, evacuation and drainage of an abscess are but imitations of nature's own processes, he gives the indications for its employment. "In operations where there is existing peritonitis or ascites, drainage" he says "is indicated. This is especially true of cases of tubercular peritonitis." He regards its use as essential in pus cases and in extra-uterine pregnancy where we have septic matter on the one hand, and an effusion of blood into the peritoneum on the other. In his experience he has saved patients by the drainage tube in cases where the coats of the bowel or the bladder had been injured and the resulting fistula developed through the drainage tract instead of discharging into the peritoneal cavity as it would otherwise have done. "Where separation of adhesions leaves extensive denuded surfaces oozing serum and blood, or bleeding is reasonably to be expected, the tube is indicated." If the tube be frequently emptied it has power to stop the hemorrhage by the frequent drying and cleansing of the peritoneum, and also will give notice to doctor and nurse of any serious bleeding. In regard to the method of draining he says "No method of drainage in pelvic surgery is comparable to the glass suprapubic tube aided by suction." It should be frequently cleansed by means of a long-nozzled syringe. When effusion is profuse the tube should be emptied at first every fifteen minutes, gradually increasing the interval as the quantity discharged diminishes. When peritoneal drainage is conducted in the proper manner it is thoroughly efficient, and he has never known septic infection to occur thereby. He does not include pelvic drainage *per vaginam* in the paper because he considers it both inefficient and dangerous—"inefficient because rubber and gauze will be obstructed, and glass is impracticable; dangerous for the reason that the tube and the opening cannot be kept clean."

Dr. Charles Dixon Jones contributes a paper on the

Development of the Placenta in Tubal Gestation

in which he comes to the following conclusions:

"1. In the earliest stages of the formation of the decidua, the folds of the tubal mucosa become enlarged, their connective tissue returns to protoplasm, their blood vessels become considerably dilated and engorged with blood.

2. Upon the approach of the decidua the columnar ciliated epithelia of the tubal mucosa enter upon a process of proliferation resulting in the production of medullary or embryonal corpuscles.

3. The medullary corpuscles are developed from previously existing columnar epithelia and in turn are transformed into decidual tissue.

4. The delicate fibrous connective tissue of the tubal mucosa is reduced to protoplasm, the stage of indifference from which decidual tissue originates.

5. The smooth muscle fibres of the tubal mucosa proliferate, produce medullary corpuscles much the same as the columnar epithelia and ultimately disappear by being transformed into decidual tissue.

6. In the third month of tubal pregnancy a lively new formation of placental villi takes place, first by a thickening, afterward by a budding-out of the older villi.

7. These buds are protoplasmic in nature and are identical in their structure with that of the epithelial layer which gave origin to them. At first the buds are non-nucleated; later on they become supplied with nuclei.

8. The originally solid buds become differentiated into a peripheral epithelial layer and a central connective tissue layer. The latter is at first made up of medullary or embryonal tissue, and afterward becomes transformed into myxomatous tissue.

9. The capillary blood-vessels grow into the central tissue by a sprouting of the older capillary loops. The sprouts are originally solid, and in turn become hollowed out by vacuolation, thus connecting with the older blood-vessels."

The paper is illustrated by cuts showing the conditions spoken of in the above resume.

Dr. James F. W. Ross reports a case of

Complete Hysterectomy,

being the second case of pregnancy complicated by fibroid tumor that has occurred in his practice within ten months. The patient was forty years old, had been married eleven months but had never been pregnant. Menstruation had been suppressed three months. She had noticed a lump in the side one month before the menstruation ceased, but it had never caused her any pain although it had increased to the size of a fetal head when the reporter saw her. The diagnosis made at that time was pregnancy complicated with either a multi-locular ovarian cyst or a fibroid tumor. At the operation it was found to be a fibroid springing from the left side of a four months pregnant uterus. Complete extirpation of the uterus was performed after the method advocated by Dr. Eastman. The tumor was drawn out; the broad ligaments tied on each side; a temporary clamp applied and the tumor cut away. An Eastman staff was then passed into the vagina and cut down upon from above through the cul-de-sac of Douglas. One finger was then passed into the vagina and the inter-abdomino-vaginal tissue sutured and cut; in this way removing the entire uterus. The ligatures were then caught together by a pair of forceps, passed up from the vagina, and drawn down together with a twisted rope of iodoform gauze. "The iodoform gauze and sutures were thus lying in the vagina, and the serous surfaces of the peritoneum surrounding the opening were approximated by this funnel-

ling of the hole where the cervix had been." The patient recovered from the operation but died on the thirty-ninth day of intestinal obstruction, during Dr. Ross's absence from home. The report is illustrated with a photograph of the tumor and fetus removed.

Dr. J. Wesley Bovee reports a case of "Complete Rupture of the Uterus during Labor." The patient had had seven children at term, and one miscarriage at three months, which occurred subsequent to an amputation of the cervix for cancer. On examination the child was found to be presenting by the vertex in L. O. A. position; the cervix uteri surrounded by undilatable, cicatricial tissue. It was decided to let labor go on and assist in whatever way seemed best. The pains continued feeble and the patient was kept in bed. Later profound and sudden collapse occurred and on examination the uterus was found to have ruptured. The post mortem showed the tear to be in the left side of the cervix posteriorly and extending from about an inch from the cervical opening upward four or five inches. "Connected with this opening was a tear through the roof of the vagina behind the uterus extending backward and to the right about two inches. The uterine wall was very soft and flabby, and its inner surface covered with a greyish, grumous material having no particularly offensive odor. No evidence of hemorrhage was found. The os uteri was very little dilated and was surrounded by a thin, circular band of cicatricial tissue." The reporter thinks the cicatrix, following the amputation of the cervix and the application of cautery, was the exciting cause of the rupture. He advises hysterectomy, either vaginal or abdominal, for cases of malignant disease of the uterus wherever it is possible.

Dr. Alfred Bland Tucker reports a "Case of Lumbar and Inguinal Hernia of the Right Side." The mass, weighing about forty pounds, extended from the umbilicus outward, corresponding with a line drawn from the axilla to the middle of the crest of the ilium, and reached to within three inches of the knee. The patient made a complete recovery from the operation. The points of interest in the case are: "1st, that there was a double hernia, the inguinal and the rarer lumbar; 2d, the contents of the sac—all of the small intestine, caput coli, part of ascending colon, and the stomach; 3d, the great displacement of the stomach from the epigastrium to a point below the crest of th eilium, and out of the abdominal cavity; 4th, the great elongation of the œsophagus necessary to reach that point; 5th, that there should not have been more disturbance of the digestive organs by the displacement." So far as the reporter is aware there is not on record a case of escape of the stomach in lumbar herniæ. The engraving accompanying the report shows the patient's condition very clearly.

Dr. Sigmar Stark discusses the

Role of the Pessary in the Cure of Retrodisplacement of the Uterus.

The cause of the displacement he holds to be a relaxation of the sacro-uterine ligaments, due to subinvolution of these folds, and being part of the uterine subinvolution. He believes that it requires more skill to properly adjust a pessary than to perform the many operations devised for the relief of the trouble. "To apply a pessary for retroflexion or version with coexisting peri-uterine inflammation of whatever character, is positive malpractice. The disease of the appendages must first be reduced, the organs rendered painless to the touch and the uterus become freely movable before recourse to the pessary may be taken." He believes the action of the pessary to be due to a pressure on, and consequent reduplication of, the sacro-uterine ligaments and gives the reasons for this belief. The aim should be not to apply a pessary till the patient is in a condition to wear one, to select a suitable instrument, and not to allow her to wear it too long. Some cases cannot be cured by the use of a pessary. In those in which the fundus is constantly tipping over the posterior bow of the pessary, we have an unstable condition of the fundus—a true joint at the junction of the cervix and the body due to atrophy. The second class of incurable cases are those in which there has been such atrophy of the folds of Douglass that restitution is out of the question and we have to be satisfied with the simple mechanical effects.

Dr. Hiram N. Vineberg concludes his paper on

Pelvic Massage in Gynecological Cases,

begun in the February number. He reports an additional number of cases treated by this method, illustrating the paper with drawings of the conditions existing in each case at the time of treatment. He comes to the following conclusions: "1. Pelvic massage is a most valuable therapeutic measure in a large percentage of cases of gynecological affections. 2. If properly applied in the cases where it is indicated, it is a thoroughly safe measure. 3. Cœliotomy and ventro-fixation for displacements of the uterus and for residua of inflammatory processes, are unjustifiable until the case has first been subjected to a thorough trial with pelvic massage. 4. It must entirely replace Schultze's method, which is a dangerous proceeding, limited in its application and not nearly as efficient in breaking up adhesions of long standing. 5. Of all methods and surgical procedures for the treatment of adherent and displaced pelvic organs, it must rank as the ideal one, calling for no mutilation and for no fixation of organs. The latter is in itself pathological, as Nature has given these organs, especially the uterus, a wide range of mobility."

Dr. E. W. Mitchell contributes a paper on

Rigidity of the Os Uteri.

The various causes of this condition are discussed and the following treatment advocated. Any malposition of the presenting part should be corrected. Dilatation by the finger may be useful at times, but care must be taken that the manipulation does not produce or intensify spasm of the circular fibres. The colpeurynter he considers much more

safe and efficient than the fingers, but must be used with the strictest antiseptic precautions. If the dilatation is prevented by adhesions between the membranes and the cervix, they can be released by gently sweeping the finger around the inner surface of the os. The use of ergot is condemned. Electricity, quinine in doses of ten to twenty grains, the hot douche, have all done good service in this condition. Opium is useful when the pains are weak and "teasing," by giving the woman rest and recuperating her powers. When it is not desired to stop the pains he has found of use chloral, administered after Playfair's rule of fifteen grains every twenty minutes for three doses, and not more than sixty grains during the labor. When chloral has failed to secure relaxation, chloroform inhaled during the pains may succeed. When a reasonable trial of other measures has failed, incisions of the rigid os may be made at several points, one-sixth to one-fourth of an inch deep, under antiseptic precautions.

Dr. Mary Almira Smith reports a case of "Malignant Neoplasm of a Lumbar Lymphatic Gland simulating an Ovarian Cystoma."

Dr. T. Ridgeway Barker discusses "The Mechanism of Labor," illustrating his paper with diagrams showing the positions of the head and shoulders in their passage through the pelvis.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY

for March contains a paper by Dr. Joseph Price on "Dermoids." The author reviews the recent literature of the subject and pleads for clean, rapid, thorough surgical work in their removal. Irrigation he considers essential. For tying the pedicle pure Chinese twist silk, as fine as possible, should be used. The sutures should be of silkworm gut, placed three or four to the inch and passed with care, including more aponeurotic and muscular tissue than skin or peritoneum. The best work is done with the fewest instruments.

Dr. B. F. Baer reports a "Large Solid Tumor of the Ovary, complicated with Malignant Disease of the Uterus." The diagnosis at first was fibroid tumor, though Dr. Baer suspected malignancy. At the operation it was found to be a solid tumor of the ovary with accompanying malignancy of the uterus. A supra-vaginal amputation of the uterus was done, and twenty days later the stump of the cervix removed by a vaginal operation. The patient recovered.

Dr. T. Ridgway Barker discusses "The Coagulability of the Blood in Parturition as a Factor in the occurrence of Post-partum Hemorrhage." Post-partum hemorrhage is due to the non-contraction of the uterus and the failure of the blood to coagulate in the uterine sinuses. The author points out that should the blood escaping from the vulva during labor fail to coagulate on exposure to the air, we may take it as a warning that the patient is exposed to the danger of hemorrhage. Fresh air and sunshine and judicious exercise during pregnancy, combined with good food are, in the author's opinion, important in the prevention of the accident.

Dr. Andrew F. Currier contributes a paper on "Certain Forms of Septicæmia Resulting from Abortion," which was published in the MEDICAL AND SURGICAL REPORTER Feb. 11, 1893, page 214.

Dr. A. T. Cabot presents

A Report of Cases of Tubal Pregnancy, with Remarks on the Choice of Operation.

He confines his remarks to cases of ruptured tubal gestation, as they have been the only form he has met with. He is of the opinion that laparotomy done at once, even in cases where no rupture has taken place, is a much safer method than any of the so-called conservative measures. When rupture has taken place there is manifestly one course only—laparotomy. No time is to be lost; a knife and ligatures are practically the only instruments required, so that the operation can be performed with simply a pocket case if necessary. "If the clots cannot be satisfactorily washed out of the abdomen with hot water, it is well to introduce drainage into the pelvis for a day or two." He then reports four cases with typical histories, three of which had had a miscarriage some time previous to the tubal gestation, and one who had a long period of sterility (six years) before the occurrence of the accident.

Very interesting in this connection is the report of a

Case of Extra-Uterine Fœtus Successfully Extracted by the Operation of Lithotomy,

reported by Dr. Joseph Bossuet, and contributed by Prof. T. Gaillard Thomas from the author's original manuscript. The case, which occurred in 1807, presented all the symptoms of missed labor which were controlled by large doses of opium. At the roll of three years she experienced acute pain in the abdomen, attended with profuse evacuations from the urethra of very fetid yellow matter and some very small bones. A communication between the bladder and rectum also developed. In 1816, lithotomy was performed and 146 bones of a fœtus, about seven months old, were extracted together with "a stone about the bigness of an olive." The author states that she then regained her health although the communication between the bladder and the rectum did not entirely close.

Dr. J. J. Mulheron makes a plea for "Early Trachelorrhaphy," stating that the operation at the end of two weeks is exceedingly easy of performance, and that he has not found it necessary to etherize the patient as no cutting is required but simply the freshening of the surfaces with a curette. The stitches are easily passed with a round needle through the soft tissues, and a peculiarity of the early operation is that it leaves no traces of the sutures. He uses carbolized catgut and has not yet met with a failure. The procedure hastens involution and is preferable in his opinion, to the immediate operation which he has found very difficult of performance.

Other papers are: "Variations of Gestation" by Dr. T. C. Hays; and "Pelvic Inflammations following Parturition" by Dr. J. G. Biller.

In the Department of Pædiatry, Dr. J. Madison Taylor reports a "Case of Hypospadia; Enormous Dilatation of Bladder; Absence of Left Kidney; Death" illustrating the paper with the photograph of the patient.

Dr. W. Henry Price reports a case of "Sarcoma in an Infant," and "Two Unusual Cases of Torticolis" of rheumatic origin which are exceptions to the rule that the head is drawn to the affected side.

PRACTICE FOR FEBRUARY.

Drs. Hugh M. Taylor and Hunter McGuire report an interesting case of

Ectopic Gestation.

Dr. Taylor diagnosed the case and urged the importance of operation. During the conversation the patient complained of sudden agonizing pain and went into a collapse. One hour and a half later Dr. McGuire opened the abdomen, found the ruptured tube, ligated and removed it, but the patient had lost so much blood that she did not rally. Dr. McGuire believes that she bled to death in about thirty minutes. He urges the importance of operation as soon as the diagnosis is made. Mr. Taylor in his remarks on the case agrees with Dr. Tait that all ectopic gestations are primarily tubal, and that the so-called ovarian, abdominal, etc., are secondary results. But let the ectopic gestation occur where it may, the indications for treatment are the same. He thinks "that temporizing with electricity savors of shirking one's duty. To shoot a few flashes of electricity through an unknown mass claiming to have electrocuted a tubal fœtus, implies a very elastic imagination or conscience."

Dr. John Blake White contributes a paper on

Pneumotomy for Relief of Tubercular Abscess and Gangrene of the Lungs,

reporting a case where the operation was performed twice on one patient, with recovery. He condemns too diligent washing out of pus cavities, pulmonary or pleural, though he believes that irrigation is safer in gangrenous cavities, as in the case reported, than in those emiting more laudable pus. In all operations on the lungs the strictest antisepsis should be carried out. Cases of gangrene of the lung are never too far advanced for surgical interence, in his opinion. He does not consider it necessary to excite pleural adhesion before operating, as the delay required may increase the danger to the patient. Resection of the rib is seldom required in the very young, except to faciliate the discovery of abscess in doubtful cases. Corrugated white rubber tubing was used for drainage, as this has proved more useful than the ordinary soft rubber generally employed.

Dr. Thomas H. Manley, in an article on

Urethrectomy, Partial or Complete, as a Method for Radical Treatment of Rupture of the Urethra, Fistula, or Organic Stricture,

comes to the following conclusions: In all cases of traumatic rupture of the perineal urethra, the tissues should be laid open at as early a date as possible, and the continuity of the lumen of the urethra should then be entirely restored by a urethrorrhaphy. Those urethral perineal fistulæ which resist dilatation or other tentative measures, should be resected and continuity restored in the passage by homologous approximation of the separated edges, the hiatus remaining being obliterated through linear elongation of the fibres of the muscular coat. With those strictures rebellious to tentative methods, not appropriate for internal urethrotomy or divulsion, when they are divided by an external incision, the occasion should be utilized to hew a gutter through the cicatrical tissues, and to reconstruct the floor of the canal with the adjacent connective tissues. In all cases the most rigorous asepsis should be employed, and the aim, in every case, should be to secure non-supurative, primary union.

The remaining article is a clinical lecture by Dr. Robert T. Morris on "The Middle Scar Hair-lip operation, and Dupuytren's Contraction."

SELECTED FORMULÆ.

Laundry Starch Polish.

In answer to a correspondent the *National Druggist* gives the following information about laundry starch polish:

℞

Stearin	25 parts
Spermaceti	200 parts
White wax	100 parts

Melt together, and while melted stir in ½ grain of ultramarine to each ounce of the mixture. (As liquid blue is u ed with most starches the latter may be omitted.) Let cool and cut into little blocks weighing about 2 drams each. One of these bits may be added to each ¼ pound of starch used. The starch may be allowed to soil for fifteen minutes before adding the gloss, and the boiling should be continued for at least five minutes longer.

Gonorrhœa in Females.

Dr. Horwitz recommends the following treatment:

℞

Ung. cucumis	ʒj
Alum	ʒj
Acid, tannic	ʒij
Ft unguentum	M.

Smear a quantity on a pledget of cotton, pass it into the vagina at night; remove it in the morning, and use the following injection:

℞

Decoct. quercus alb	Oj
Sodii boratis	ʒss M.

—*Ex.*

Vomiting in Pregnancy.

Dr. Frank R. Fry recommends the following :

℞
Cocain. muriat..... grs. vj.
Cerii oxalat..... grs. xxiv.
Glycerinæ, } aa..... ʒiij,
Aquæ laurocer, }
Aquæ destil. q. s. ad..... ʒiij,

M. Fiat mist. Sig.—One tablespoonful (taken cold) every two hours once or twice a day, pro re nata.

—*Coll. and Clin. Record.*

Sore Throat.

The following is recommended in the tre atment of sore throat :

℞
Cocainae hydrochlorat..... grs. viij.
Acid. carbolici..... ʒi.
Glycerinae..... fʒiv.
Aquae rosae q. s., ad..... fʒxii.

M. Sig.—To be d luted with an equal quantity of water, and used alternately as a spray and gargle.

—*Medical Progress.*

Local Psoriasis.

Pyrogallic acid, salicylic acid, chrysophanic acid, ichthyol, aristol. each ℈j ; axonge, ʒiss. To be applied once a day.

—*Med. Press and Circut.*

Barber's Itch.

℞
Tannic acid..... 45 grains.
Lac sulphur..... 1½ drachms.
Zinc oxide } of... ....
Starch .... } each..... 4 drachms.
Vaseline..... 1 ounce.

Make into an ointment and use twice daily.

—*Phar. Era.*

Antiseptic Dental Cream.

H. L. Hurxthal has been awarded a prize by the *Pharm. Record* for the following formula :

℞
Precipitated chalk..... 5 drams.
Powdered white castile soap. 1 dram.
Salicylate of soda..... 30 grs.
Oil of rose geranium..... 4 drops.
Oil of wintergreen..... 4 "
Solution of carmine..... 2 "
Glycerine, 4 }
Water, 1 } .... q. s.

Taenifuge for Children.

—ELECTUARY.—

℞
Male fern extract..... 4 gms [1 dram]
Calomel..... 0.3-0. 4 gm [6grs.
Powdered gelatin } sufficient quantity of each]
Powdered sugar }

For one electuary. To be taken before breakfast.

(The day preceding the administration of the medicament, the child should take nothing but milk ; in the evening of the same day an enema of Senna Infusion is given, followed a few hours later by an injection of plain water. The next day, the child takes the confection. If the expulsion of the worm is tardy, a salt-water clyster is given (Salt 40 grammes [10 drs.], Water 200 grammes [6¾ fl. oz.]) two or three hours after the ingestion of tænifuge.

—*Ex.*

Treatment of Gonorrhœa.

The following will be found useful :

Salol, ʒiv. Divide into twelve powders ; three daily. Ichthyol, 1 ; water, 100. Three injections daily. Ichthyol is found to be superior to sublimate or permanganate of potass.

Treatment of Impetigo Contagiosa.

Besnier's application in impetigo contagiosa and pustulous exzema is as follows :

℞
Salol..... 3 gm.
Sulphuric ether..... 3 gm.
Cocaine hydrochlorate..... 20 cg.
Collodion ..... 20 gm.

Mix and make a collodion. Apply to the diseased parts after carefully drying same

Pomade for Psoriasis of Scalp.

Besnier gives the following :

℞
Potash soap..... 20 gm.
Vaselin ..... 20 gm.
Ichthyol..... 2 gm.
Salicylic acid..... 1 gm.
Pyrogallic acid..... 1 gm.

Mix and make a pomade, which is to be applied every day to the plaques of psoriasis. If much irritation is created, suspend the application temporarily.

—*Nat. Druggist.*

Soothing Syrup without Opium.

℞
Oil anise..... mxxv.
Alcohol..... ʒij.
Fl. ext. valerian..... ʒi.
Oil peppermint..... mxv.
Tinc. camphor..... ʒij.
Fl. ext liquorice..... ʒi.

M. Sig.—Shake the bottle. Dose, one-fourth or one-half teaspoonful in water ; repeat as needed.

—*Med. Age.*

Prof. Hare recommends the following prescription in cases of *Gastralgia:*

℞
Tinct. capsici.....fʒij.
Tinct. cannabis indicæ.....fʒss.
Tinct. opii deodorat.....fʒj.
Spirit. chloroform.....fʒj.
Spirit. lavend., q. s. ad.....fʒiv.

M. Sig. Teaspoonful every thirty minutes until relief is obtained.

Vesical Injections of Emulsions of Iodoform in Purulent Cystitis.

Dr. Philippoff (*Deut. Med.-Zeit*, No. 93, 1892) has used vesical irrigations of an emulsion of iodoform in the treatment of purulent cystitis, and is gratified with the results obtained in three severe cases. He first washes out the bladder with a solution of lactic acid (1:400), and then injects twenty grammes (5 drachms) of the following :

℞
Finely powdered iodoform....gms. 5 (¼ʒj)
Mucilage of gum arabic.....gms. 2 (gtts. xxx.)
Pure Glycerine.....gms. 8 (ʒij.)
Distilled water, ad.....50 gms. (ʒjss.)

The injection is retained for fifteen minutes. They are repeated at intervals of several days, and continued for a number of weeks. Internally salol and Vichy water are given. With this treatment Phillippoff had observed no symptoms of poisoning, due, he says, to the vesical mucous membrane being changed by the pathological process.

PERISCOPE.

MEDICINE

Heat in Local Skin Diseases.

Stepanaw (*St. Petersburger Medicinische Wochenschrift*), writes the following as the outcome of his investigations:

1. In the treatment of local skin diseases and ulcers, heat is an important factor.
2. Ulcers heal more rapidly in consequence of the application of heat than under any other treatment.
3. Heat acts as well upon syphilitic as upon non-syphilitic ulcers.
4. The beneficial effects of heat on the healing of ulcers depends principally upon regulating the circulation and improvement of the nutrition of the diseased parts.
5. Under the influence of heat, local congestion rapidly disappears.
6. Heat acts as a sedative.
7. Heat acts the better the longer it is applied (6 to 8 hours daily).
8. The application of heat by means of the rubber bag with hot water, is preferable to other methods. Even prolonged use of the bag does not produce blistering.—*Medical Era.*

Varicose Ulcers.

EUROPHEN.—Gilbert (Reprint from *Balneologisches Centralblatt*, Vol. II, No 13,) reports two cases of varicose ulcers treated with europhen.

I. Woman aged sixty-nine. Hard infiltration and eczematous inflammation of entire left foot and leg; ulcer the size of a human palm, covered with flaccid, torpid granulations. All previous treatment proved ineffectual.

II. Woman aged fifty-five. Ulcer 4 cm. ($1\frac{5}{8}$ inch) long by 3 cm. ($1\frac{3}{8}$ inch) broad, entirely surrounded by inflammatory indurations; varicose veins near the ulcer.

Treatment.—Local bath of chamomile flowers in the evening, sprinkling the entire surface with europhen, light covering with gauze and cotton-wool, and enveloping with muslin bandage. In the morning application of europhen ointment.

℞ Europhen.....2.0 (ʒ ss)
Vaselin.....
Lanolin..... aa 50.0 (ʒ xii ss)
M. f. ung.

This application was again covered and the leg bandaged. Soon healthy granular tissue appeared in both cases, and in three weeks the ulcers were covered with skin. There was no recurrence of the ulcer in either case. —*Cinn. Med. Jour.*

SURGERY.

How to Administer Chloroform Properly.

Mr. W. J. Cleaver gives the following valuable advice in regard to the administration of chloroform: Take your folded towel or cap of flannel stretched over a wire frame, and your chloroform bottle, graduated if you like, but this is of no consequence: let the temperature of the operating room be at least sixty-five degrees F.; if your patient be one of the very nervous kind, give from half an ounce to an ounce of brandy an hour beforehand; put your catch forceps or your tongue forceps on the pillow beside you; pour a dose of chloroform, a drachm or two, on to the towel or cap and hold it, to commence with, two or three inches away from the mouth and nose of your patient, gradually bring it nearer, but never so near as to exclude air from mixing with the chloroform vapor; at the same time keeping your mind and eye on the respiration movements alone. If the patient shows any symptoms of struggling, let assistants take hold of his wrists and allow him to move his arms about as long as he does not interfere with the administration. If he endeavors to get up he must, of course, be restained, but on no account let half-a-dozen dressers throw themselves upon him, their united weight probably coming near upon half a ton. What chance has free respiration in such a case? A little pressure on the shoulders will in ninety-nine cases out of a hundred be found to be quite sufficient; when a patient is forcibly held down with half a dozen big men on top of him, his struggle ends in a kind of night-mare, with perhaps a fatal shock at the close of it. Continue the administration quietly and gradually, without being put out of countenance by the repeated demands of the operator—to know whether he is not yet under; and such remarks as, I never knew a man take such a lot, put it closer to his nose, what a time he is getting under, etc., etc. You are giving the chloroform, not the operator, therefore take no heed of him. When there is no conjunctival reflex, and a pinch on the skin of the abdomen bears no result, the pupil of the eye fairly contracted, and the breathing regular but perhaps stertorous, you can allow the operating surgeon to proceed.

Pay no attention to the operation, however interesting it may be; watch your patient's breathing only, and continue the chloroform when you see any signs of returning consciousness. If you do this, and this only, you will never have cause to regret it.—*Sheffield Med. Jour.*

Carbolic Acid in Surgery.

There is considerable excitement in surgical circles just now owing to the recantation of Sir Joseph Lister in regard to the use of carbolic acid and mercuric salts in surgery. He has now abandoned the latter entirely, and has gone back to the former. The fact was mentioned in *The Chemist and Druggist* a few months ago (November 5, 1892, page 681), but the medical papers have just got hold of it through an address delivered by Sir Joseph at King's College the other week. It seems that the reason why corrosive sublimate began to displace carbolic acid was be-

cause Koch made some observations which showed that the former was more powerful than the latter; but it turns out that Koch exaggerated the power of the sublimate, and in such solutions as can be used in surgery it is much inferior to the acid in bactericidal power. Professor Crookshank has made experiments with the two antiseptics upon the tubercle bacillus, which further demonstrate the superiority of carbolic acid. So much for what may be called the theory. In practice Sir Joseph Lister uses a 1-in-20 solution of carbolic acid, and he states that while "it is more trustworthy as a germicide for surgical purposes than corrosive sublimate, it is in other respects also greatly to be preferred. Carbolic acid has a powerful affinity for the epidermis, penetrating deeply into its substances, and it mingles with fatty materials in any proportion. Corrosive sublimate solution, on the other hand, cannot penetrate in the slightest degree into anything that is greasy; and therefore, as the skin is greasy, those who use corrosive sublimate require elaborate precautions in the way of cleansing the skin—treating it with oil of turpentine or ether, not to mention soap and water, to remove the grease which they feel it essential to get rid of for the efficient action of the corrosive sublimate. All this is unnecessary care if you use carbolic lotion." It is satisfactory to note that the founder of Listerism has gone back to his old faith. It deserves to be mentioned that for several years the quantity of corrosive sublimate used in the principal hospitals of London has been on the decrease, and carbolic acid has been taking its place. The reason for this has not been exactly that put forward by Sir Joseph Lister, but the fact that mercurial poisoning was becoming very frequent amongst surgical patients. This was due, of course, to the corrosive sublimate being pushed too far, as, indeed, antisepism is apt to be. There is a growing belief that asepism rather than antisepism will hold the surgical field in the future.—*The Chem. and Druggist.*

Suture Applied to Wounds of Veins.

Dr. Max Schede (*Einige Bermerkungen ueber die naht von Venenwunden Arch. fur. Klin. Chirurgie* No. 3-4, 1892,) favors the application of a fine continuous catgut suture to wounds of the larger veins. He presents the case of a man who was operated upon for a malignant tumor of the kidney. During the operation the inferior cava was accidentally incised. The opening was closed by a suture that extended along the vessel for a distance of two inches. During the vein suture the hemorrhage was controlled by applying catch forceps above and below the opening and extending the vein.

The patient died several days after the operation, permitting an examination of the vein to be made. The intima had united firmly and the neighboring part of the vessel wall was perfectly normal. No evidence of thrombosis was present throughout the vessel. The author thinks suture much superior to ligature or leaving forceps upon the vein.

Two New Local Anæsthetics.

The muriate of tropa-cocaine, or tropsin, is a substance obtained from the Java coca, and said by Professor Schweiger to have a local anæsthetic action resembling that of cocaine. It is weaker in action, but it causes anæsthesia more rapidly.

Eugenol-acetamide is recommended as a new anæsthetic. As crystallized from water it occurs in lustrous scales; from alcohol it occurs in fine needles, melting at 110° F.

This compound, when applied in the form of a fine powder, produces local anæsthesia without any caustic action, similar to cocaine. This anæsthetic effect, in connection with the strong antiseptic properties of eugenol-acetic acid, secures a place for this new amide in the treatment of wounds.—*N. Y. Med. Rec.*

OBSTETRICS.

A Bacillus of Eclampsia.

The time-honored relation of albuminuria to purperal eclampsia—as cause and effect—has been questioned at various times, but as there had never been any facts presented which furnished a more plausible solution of the etiology of this serious disease, it has remained practically as before—the result of the nephritis of pregnancy.

Kaltenbach and Gerdes (*Wien. Med. Blaett., and Med. Deutsche Med. Wochen.*), and abstracted by The Review of Insanity and Nervous Diseases, have discovered a short, thick bacillus in the organs and blood of patients dead of puerperal eclampsia, and Gerdes sums up as follows:

1. The eclampsia bacillus is the sole cause of puerperal eclampsia and is found in no other disease, and there can be no eclampsia without its presence. The infection proceeds from the uterus, probably from an endometritis existing prior to conception.
2. The convulsions due to other causes occurring during labor, are to be strictly separated on the basis of the post-mortem appearances, from true puerperal eclampsia.
3. Eclampsia is a well-characterized disease, strictly limited anatomically.
4. The profound changes found in the organs of eclamptic patients *post mortem* are not adequately explained by the domonstration of the presence of the specific germ in the body, but are probably due, directly or indirectly, to its toxines.—*Chicago Clin Review.*

Excursions to Washington.

Personally conducted tours to Washington have been arranged via Royal Blue Line, to be run at frequent intervals from New York and Philadelphia to Washington. The next excursion will be on April 6th. For programme, describing these tours, write to Thos. Cook & Son, Agents B. & O. R. R., 261 and 1225 Broadway, New York, or 332 Washington Street, Boston, Mass.

PHENACETINE-BAYER

THE TESTIMONY of physicians accords to Phenacetine the first place in the list of modorn Antipyretics and Analgesics. It acts promptly and effectively within the limit of safe dosage. It lowers Fever, quiets Pain, and induces gentle Diaphoresis.

INDICATED in Pneumonia, Rheumatism, Neuralgia, La Grippe, Hemicrania, and all Febrile Conditions.

Phenacetine is supplied in ounces, also in Tablets and Pills, alone and combined with Salophon, Salol, etc.

SULFONAL-BAYER

ALL PRACTITIONER'S speak well of Sulfonal. Its action is purely Hypnotic. In small doses it is a Sedative. It is safe and reliable; it gives rise to no sequelæ and causes no drug habit. It must be given As Directed.

INDICATED in the Insomnias and the Neuroses. In painful insomnia it may be combined with Phenacetine.

Sulfonal is supplied in Ounces, Tablets and Pills Also in Tablets (2 sizes) combined with Phenacetine.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

Vaccine Matter.

For the accommodation of our Subscribers, we will supply both Bovine and Humanized Vaccine Virus.

Guaranteed to be fresh and in every respect first-class.

PRICES:

Bovine Crusts,	**$1.50 each.**
Bovine Points or Quills,	**1.00 a dozen.**
Humanized Crusts,	**1.00, small.**
Humanized Crusts,	**2.00, large.**

Nothing less than half dozen sold at these prices.

The Humanized Crusts are warranted to be from typical cases, and in every instance from healthy children, with unquestionable family histories.

Please accompany the Order with the Money.

ECLAMPSIA OF PREGNANCY.

I. C. BARNES, M. D., Topeka, Kan.

Authors vary as to the limitation of the term eclampsia; some confining it simply to clonic convulsions which may be idiopathic, symptomatic or sympathetic. But the eclampsia of pregnancy is recognized as having a significance peculiarly its own, due to existing complications in which loss of consciousness, tonic and clonic convulsions and coma follow each other in rapid succession.

While the eclampsia attacks may not be precipitated until labor occurs, or may of itself be sufficient to produce premature labor, or is delayed until the puerperal period, still it must be ascribed to conditions existing during pregnancy otherwise beyond the domain of eclampsia as defined by the obstetrician.

It is not my purpose to impose upon the members of this association by detailing the various theories which have been advanced from time to time to explain the phenomena of eclampsia.

You are all familiar with them, as also with the effect that no sooner has a theory been promulgated and seemingly firmly established upon tenable grounds by its originator, than other observers have presented a line of cases similar in nature and occurring under similar conditions, but ascribing a causation partially or wholly based upon deductions derived from very different physiological and pathological standpoints, and thus have formulated theories which have varied as widely.

It cannot be said that all or any of such deductions are absolutely without foundation, but that error has been made by dwelling too emphatically upon some one phase or manifestation or pathological condition to the exclusion of all others, and of confounding the results of certain conditions with causation; as for instance, ascribing the unconsciousness and coma to a primary anæmia of the brain centres rather than to an anæmia due to vasomotor spasms.

Also so subtile is the human mind, that waves of theories like fancies flit before the vision, and apparently fulfill all the demands that the manifestation of disease requires, but sooner or later the delusion is vanquished by the observation of real facts relating to the etiology of the disease, and these fallacies are expunged.

Again, cases will arise that will not accommodate themselves to any classification, and are known as the exceptions, exhibiting the same phases, but lacking the pre-eminent pathological and physical conditions necessary to ally them with *bona fide* cases.

While true theories very materially aid in the scientific treatment of disease, false theories likewise as greatly mislead, and since all theories are based upon more or less thorough research and the deductions derived therefrom, it follows that the more this research is aided by the modern appliances of minute workmanship in chemical, bacteriological and pathological departments, the less frequently will the etiology of eclampsia be ascribed entirely

to the failure of function of one organ of the body, precipitating upon the system toxic products from the non-elimination of effete material, producing irritation of the central nervous system and thus exciting vasomotor spasms, peripheral irritation due to pressure on tense tissues, or to the hydræmic condition of the blood during pregnancy, or to a neurosis, any more than can be estimated just the amount of disorder and irritation necessary to bring about a climax in certain individuals under other circumstances.

However, investigation of each case, with regard to all details, will enable an approximate estimate to be made which shall ascribe to the different complications existing, a proportionate degree of causation which for a certain period of time, in a certain individual, will destroy consciousness and furnish a stimulant to the vasomotor centres sufficient to set in tonic and clonic contractions the voluntary muscles of the body and thus impede circulation and respiration to a degree that endangers life.

It is not only important to know that a sufficient number of cases have presented symptoms and phases similar in character, and that pathological investigation warrants the explanations which have been made relative to the convulsions due to specified conditions existing during pregnancy, but also to allow latitude as we are obliged to in the etiology of all other diseases in ascribing a symptom to this or that departure from the normal balance of the human system.

Now, it is found that the great majority of cases exhibiting this phenomenon have albuminuria, and that the albumen is due to an acute attack of inflammation of the kidney or to a chronic inflammation upon which is superimposed an acute attack or a congestion, all of which give rise to a more or less complete suppression of urine; but it is also established beyond controversy, that not every woman that has albuminuria during pregnancy will have eclampsia; and that also complete suppression may exist without any untoward results, and that partial suppression is frequently unaccompanied by albumen in the urine.

Still, as a rule the greater number of eclamptics are albuminuric and they do have partial or complete suppression. So that the physician is enabled to successfully ward off many attacks by promoting the secretion of the inactive kidney and securing the elimination of products of disorganization through other channels.

This, as a preventative measure, is of prime value; but as an expedient of relief at time of attack is secondary to normal labor, or labor artificially produced. Hence, the gravity of the case is relative to the length of time supervening between the attack and the completion of pregnancy.

That to the kidney lesion only as a complication of pregnancy, can be ascribed such a certainty of serious results suddenly overwhelming the patient, is demonstrated by the fact that such a lesion existing without this complication does not usually give rise to convulsions unless in very advanced stages.

Some few cases exhibit clearly the neurotic element, in which the discomforts and complications of irritation due to pregnancy are sufficient to excite an explosion of nerve energy; or may properly be ascribed to causes independent of pregnancy, and, therefore, a coincident rather than a result.

It is difficult to understand why convulsions should cease upon the removal of the ovum from the uterus, since the kidney condition still remains unless the pressure of the pregnant uterus proved a sufficient cause to excite an already overcharged nervous system, or that blood pressure was lowered by the relief of distention of the abdominal parietes and more or less compression of abdominal viscera, permitting a filling of the blood-vessels of this region of the body so capable of draining the system of a large portion of its circulating fluid and accomplishing the result more effectually than by means of diaphoretics, purgatives and venesection.

This general relaxation secures greater amenability to therapeutical remedies, and in the majority of cases in the beginning of recovery, opening the way for relief of all other complications.

The complete or partial suppression of urine, which has herertofore resisted all efforts to induce secretion, is gradually relieved.

It would be rather difficult to explain why convulsions, if due to toxæmia alone, cease as soon as the uterus is emptied of its contents, while complete suppression

of urine still exists and consequently there has been no opportunity for the system to unload itself of the retained products of excretion except by the alimentary and cutaneous surfaces, which have hitherto proved ineffectual.

It is easier to see why the coma should become less profound and gradually disappear as the secretion of the kidneys resume normal sway and the power of elimination is gradually increased.

A variety of phenomena usher in an eclamptic attack, some of which are peculiar to eclampsia while others are common to many diseases, both organic and functional, and thus frequently allay suspicion unless care is taken to seek the cause of every symptom, subjective and objective.

The most obvious premonitory symptoms, however, are followed so closely by the attack that not much time is given to relieve the vasomotor tension by depletion through the alimentary and cutaneous surfaces, so that very frequently all efforts to avert are futile.

The same measures are employed for relief as for prevention, with the addition of venesection for immediate effects, and induced labor when all other means have failed.

It is not only a procedure to save the life of the mother but also that of the child which will not survive oft repeated attacks.

Unfortunately the cessation of eclampsia does not always secure uninterrupted restoration to health, since so serious complications accompany or follow that no available resources are able to restore the normal equilibrium.

The gravity of the case bears a somewhat constant relation to the number of convulsive seizures, the greater the number the more unfavorable the prognosis.

REPORT OF CASE.

The case that came under my observation at the Hospital two years ago presented the following characteristics:

The patient was comatose when my colleague arrived, with a history of several convulsions in the last six hours, at the beginning of which, she relapsed into an unconscious condition from which the attendants were unable to arouse her.

A physician in the vicinity was called in, who gave her a purgative and left a sedative mixture with the advice to the friends to get her into a hospital.

Three hours later a message was sent for assistance without specification as to kind.

I was detailed to attend the case which I supposed to be an instrumental delivery; but upon arrival found the condition of affairs as mentioned.

Vaginal examination revealed a cervix of considerable length, an internal os completely closed, with no fixation of presenting part—in fact no attempt at delivery.

The convulsions were typical, and ten were reported within three hours. The bowels had been moved by an enema and the catheter passed but no urine obtained.

An anæsthetic was given at time of convulsions, and also two hypodermics of sulphate of morphia of $\frac{1}{4}$ grain each, during afternoon.

There was no convenience for baths or necessary care in the lodging house of the tenement quarters in which the patient was found, and the only chance for successful treatment lay in the possibility of getting her into the hospital.

Although fearing that the ride in the ambulance of five miles over cobble stone streets, might excite convulsions of so great severity that death from asphyxia would result, yet the journey was accomplished with very little inconvenience and no symptoms of increased irritation were present. The one convulsion came about the regular interval and did not surpass former attacks in severity.

At 7 P. M. arrived at hospital and the patient was immediately placed in a hot bath which was prolonged half an hour. She had two convulsive seizures during the time. A hypodermic of sulphate of morphia $\frac{1}{4}$ grain, was given and a drop of croton oil on tongue.

Phlebotomy of left arm was attempted but unsuccessful, the blood either would not flow, or the incisions were made into superficial veins rather than the deep ones.

Potass-bromide sixty grains and chloral twenty grains, were given by rectum and at 8.20 patient replaced in hot bath and removed in ten minutes.

A few minutes later had two convulsive attacks in quick succession.

Phlebotomy of right arm attempted with little success.

At 8.45 patient had a very severe convulsion and was replaced in hot bath to be removed in ten minutes to a hot pack.

Twenty minutes intervened when convulsive seizures returned.

Vaginal examination revealed the presenting part high, considerable cervix and no attempt at dilatation of the internal os. After some manipulation in this direction an attempt was made to introduce a Barnes dilator, but unsuccessfully.

Forty minutes later there was a severe attack lasting 1¾ minutes.

Patient again placed in hot bath—seventy-two minutes later two more severe seizures, seventeen minutes apart and lasting one and one-half minutes. The pulse 170 and respirations 40.

At 10.33 P. M., a soap and water rectal injection was given and retained.

Fourteen minutes after there was a convulsion of the right side only. Patient was taken from bath in which she had been placed and a catheter passed but no urine obtained.

Dry cups placed over the kidneys and a hypodermic of one-sixth grain of pilocarpin given.

11.56 P. M., A convulsion of right side only and in sixteen minutes another which, in twenty minutes, was followed by a general convulsion.

The temperature was 105.2° A hypodermic of morphine sulphate one-fourth grain was given, and Barnes' dilators successfully introduced. There being a slight attempt at dilatation, this was followed by a convulsion.

Patient placed in hot bath; thirty minutes after there was another convulsion, followed in thirty-five minutes by a convulsion of right side; was taken from bath and put into hot packs and catheter passed but no urine obtained.

Soap and water rectal injections given and retained. In fifty minutes there was a convulsion of right side. The water from retained injections was drawn from the bowel with a rectal tube.

Fifty minutes later a general convulsion supervened. The temperature was 104.6.°

At 6.30 A. M., February 16th, the chloroform which had been given since admission to relieve the intensity of convulsions was increased until complete anæsthesia prevailed. The membranes were ruptured and version attempted but abandoned.

Artificial dilatation being sufficient to deliver, forceps were applied, the head, which was the presenting part, fixed and craniotomy performed. This permitted artificial delivery.

Lacerations of the cervix and perineum were remedied by primary operations. Complete suppression of urine still existed.

A hypodermic of ergot, the fluid extract, twenty-five minims was given, and a ten-grain quinine suppository.

The pulse was 200. A hypodermic of digitalis and also one of pilocarpin was given half an hour afterwards with cups over kidneys and steam bath.

At 9.20 A. M. the catheter was passed and obtained a small amount of urine the first in twenty-four hours, or rather since the patient was taken in charge.

The convulsions ceased immediately upon delivery. Hypodermics consisting of tr. of digitalis five drops and aromatic spirits of ammonia five drops, were given every two hours through the day. Quinine suppositories, five grains every three hours. Peptonized milk given by rectum and cups applied over kidneys.

During the afternoon the restlessness and muttering delirium was relieved by bromides and chloral and cups applied to nape of neck and spine.

One-sixth of a grain of elaterium was given in butter on the tongue.

During the convulsions the patient had almost severed a portion of the left side of the tongue and the inflammation and slough served as an impediment to respiration.

At 6.30 P. M. the breathing became labored with symptoms and physical signs of congestion of the lungs, and flax-seed poultices were applied over the chest.

During the night the restlessness was controlled by bromide and chloral. The pulse was 140 and temperature 103.°

A cough mixture containing ammonium salts was ordered to be taken every two hours.

During the morning of February 17th, a steam bath was given, but since the kidneys were secreting fairly well the cups were discontinued.

About noon patient began taking food and medicine by mouth, and aroused from her coma to a degree that she was able to speak a few words intelligently; the most favorable symptoms since entrance three days before.

In the evening a hypodermic of the hydro-bromate of hyoscine was given, $\frac{1}{100}$ of grain for restlessness.

The pulse was 130 and temperature 104.6.°

The secretion of urine since three hours after delivery gradually increased in quantity, although the albumen fifty per cent. of specimens examined failed to diminish perceptibly. Hyaline, granular and fatty casts were abundant; also blood and granular debris.

During the earlier hours of the evening, however, the pulse became more feeble and respiration more difficult and the coma, which had been partially relieved, deepened, and at 2 A. M., February 18th, the patient died.

Post-mortem examination revealed the lungs œdematous, abdomen filled with dropsical fluid, chronic parenchymetous nephritis with evidence of acute attack.

No examination of the brain was made.

(The pregnancy was eight and one-half months advanced and the lochial discharge normal in quantity and consistency —there being no tendency to excessive hemorrhage.)

There were thirty-six convulsions from noon February 15th, to the morning of February 16th, at 6.30 A. M., with a probability of ten to fourteen before the physician arrived, making about fifty in all and thus coming in the scope of the mortality of fifty per cent. as recognized by the best authorities.

CLINICAL LECTURES.

SENILE AND SECONDARY CATARACTS AND THEIR TREATMENT.

EDWARD JACKSON, A. M., M. D.*

Gentlemen: We will to-day consider the operative treatment of cataract, different phases of which are illustrated by some of the cases to which I wish to call your attention.

SIMPLE EXTRACTION FOLLOWED BY PURULENT CONJUNCTIVITIS; RECOVERY.

Mrs. K., aged sixty years, came here three months ago, complaining of gradual failure of vision, which had progressed until with the right eye she was barely able to count fingers at two feet, and in the left eye she had only light perception. Each pupil was occupied by an opacity of the lens. With the ophthalmoscope the gray of the lens was in the right eye faintly tinged with the red of the fundus reflex, but in the left eye no trace of the fundus reflex was visible. She had in both eyes good quantitative perception of light; that is she could tell promptly and correctly when the light in the dark room was turned up or down, or brought near or removed farther from her. She had also good light projection; that is she could recognize the position of the light in whatever portion of the field of vision it was held. She had therefore senile cataract, uncomplicated and presenting all the indications for operation.

I removed the lens from the left eye by the operation which I now propose to perform on its fellow. The operation itself was without special difficulty or complication, but the next morning the lids were œdematous and the conjunctiva swollen. Within forty-eight hours there was a free purulent discharge from the conjunctiva, so that by the third day she had to be removed from the ward for operative cases for fear that other patients might be infected. On the fifth day the conjunctival discharge was so profuse that the checking of it became a matter of paramount importance, and we commenced the application of a strong solution of nitrate of silver to the everted lids. The healing of the corneal wound was not, however, interrupted, its closure and the refilling of the anterior eye chamber having occurred within the first twenty-four hours; and three weeks after the operation the conjunctival inflammation was well under control, and with the proper correcting lenses she could read part of the ten metre type at five metres.

*Professor of Diseases of the Eye in the Philadelphia Polyclinic Surgeon to Wills' Eye Hospital.

She now returns to have the cataract removed from the right eye. This I proceed to accomplish by the operation of simple extraction. I make a section of the cornea entirely within the clear corneal substance, parallel with the sclero-corneal junction and extending over almost half its circumference. Having completed the section, before laying the cataract knife aside I use its point to open the capsule of the lens. The cutting of the operation is now completed. To effect the delivery of the lens I take in the right hand a tortoise-shell lens scoop with which to make pressure on the eye-ball at the lower part of the cornea, and in the left hand a narrow corneal spatula with which to make counter-pressure on the upper lip of the corneal wound, if it is needed, or to aid in other ways the expulsion of the lens.

The pressure on the lower part of the cornea is made steadily backward, toward the centre of the eye-ball pushing back slightly the lower part of the lens, and being transmitted through the vitreous so that the upper margin of the lens is forced forward, dilating the pupil and entering the corneal wound. This pressure is steadily maintained and augmented until the widest diameter of the lens nucleus emerges through the corneal opening. The escape of the lens lessens the pressure within the eye, but some pressure is steadily maintained until all the cortex has escaped that can be delivered in this way.

In this case there still remains a little lens cortex within the eye, and for its removal I employ washing out of the anterior chamber with a solution of common salt by means of Lippincott's syringe. By directing the stream upon the iris it is made to straighten out in the anterior chamber assuming its normal position. During the washing you notice that quite marked contraction of the pupil has occurred, so that now we have the small circular pupil that is desired at the close of a cataract operation. Still, I will instil a drop of a solutioon of eserine sulphate one-quarter grain, to distilled water one fluid ounce, believing that in doubtful cases its influence is in the direction of preventing prolapse of the iris or its adhesion to the cornea. And to make the result most secure such an instillation is repeated at each dressing until the anterior chamber has been permanently refilled with aqueous humor.

After washing out the conjunctival sac and margins of the lids with a boric acid solution, the patient is told to keep the eyes closed very gently and this dressing is applied. Two or three thicknesses of absorbent gauze are laid on the lids and over this a light mass of absorbent cotton, and the whole held in place by strips of adhesive plaster passing across it from the cheek to the brow. This makes a comfortable dressing that protects the eye from infection, secures it rest, absorbs all discharges, makes no pressure, and is not liable to be dragged by movement of the head on the pillow, as is any form of bandage passing around the head. Its worst defect is that the plaster pulls on the skin when you come to remove it, and is liable to cause the patient to squeeze the eyelids tightly shut. You must guard against this by seeing that the strips of plaster do not catch any of the eyebrows or hairs that they can pull on, and that they are not longer than is necessary.

Such a dressing I continue to use four or five days, changing it usually twice a day, unless the conjunctiva show signs of hyperemia, which is always provoked or aggravated by the poulticing effect of a thick dressing, and whenever evidence of such an effect is noticed I replace this dressing by a couple of strips of gelatine plaster applied directly to the lids; a dressing that does not so well guard against wound infection and is rarely so comfortable, but which avoids the retention of heat and moisture that gives the thicker dressing something the influence of a poultice in causing or aggravating congestion or inflammation of the conjunctiva.

[In this eye there also developed a sharp conjunctivitis with considerable purulent discharge. It was treated in the same manner and the healing proceeded normally, the patient getting her cataract glasses at the end of four weeks, and having with them vision equal to 5-10ths mostly.]

SIMPLE EXTRACTION; PROLAPSUS OF THE IRIS.

This man, P. H., aged sixty-five, had a cataract extracted nine days ago. The lens was large and consisted almost entirely of firm nuclear substance, and this being suspected before the operation, to get as long an incision as possible I placed it nearer to the iris than the usual

point of selection. The patient, too, was restless, and during the first twenty-four hours there occurred a prolapse of the iris. The use of eserine reduced its size but did not entirely restore it, and you now see it as a brown swelling of some two millimetres in diameter at the centre of the scar of the corneal incision. It is now probably at its maximum, and from this time on will shrink until there is nothing left to mark its location but a dark speck in the line of the corneal scar.

This condition, while it is by far the most serious complication that is liable to succeed the simple extraction of cataract, is not nearly so grave an accident as might be supposed from our knowledge of the tendencies of prolapse of the iris occurring after other corneal perforations. In this connection it seems to be quite free from the tendency to go on increasing that makes it so disastrous in many cases of perforating ulcer or laceration of the cornea. This difference is probably due to the altered relations of the iris to the cornea brought about by the removal of the lens from behind it.

This absence of any malignant tendency to persistent increase or to keeping up an inflammation of the iris and related parts, leaves little excuse for any heroic treatment of the prolapse. It is neither necessary or advisable in the mass of cases to incise it or excise it, or even to touch it with the galvano-cautery. In a case of very extensive prolapse it may be proper to resort to one of these measures, but such cases are quite exceptional. You must bear in mind also that a very small part of the iris constituting a prolapse will, at a certain stage, be distended so as to look much larger than it really is, and that its apparent size will vary from time to time according to the amount of such distension. The active treatment had better be preventive, the placing of the corneal incision well in front of the iris, doing an iridectomy where the iris cannot be fully returned to normal position at the time of operation, and the regular instillation of eserine if it is so returned. Then, if the prolapse does occur some time after the operation, treat it on the expectant plan, and the ultimate result will be almost as good in these worst cases of simple extraction as it is in the average case of extraction with iridectomy.

The occurrence of prolapse somewhat protracts the process of healing, increases, at least for a time, the amount of post-operative astigmatism, and prolongs the period during which the astigmatism is diminishing, and so delays the final adjustment of glasses. But my impression is that so far as its permanent usefulness, and continued sound nutrition and freedom from liability to other disease are concerned, an eye that has suffered prolapse after the simple extraction of cataract is as safe as an eye that has suffered iridectomy during the operation.

[From this time the prolapse diminished, the eye was free from irritation by the thirtieth day when he left the hospital. Glasses were finally adjusted in the eighth week after the extraction. He required +12. sph.+3.D.cyl. axis 175° and with this he had vision=5-15ths, which can undoubtedly be improved materially by needling the lense capsule.]

SECONDARY CATARACT; OPERATION.

From this man, J. G., aged sixty-three, I removed both lenses for cataract a little over a year ago. The operation done was the simple extraction, and it has left the perfect iris and pupil that some suppose are its chief advantages, but which are usually quite subordinate to its superior safety and greater ease of accomplishment. The right eye was operated on first, and the left a few days later. In the right it was found that some opacity of the capsule or remains of cortex interfered with the result of the extraction, so the capsule in that eye was needled. He left the hospital with 5-5ths. vision in the right eye and 5-10ths. vision in the left, with his correcting glasses.

He returns now with the vision in the right eye still as good as ever, but complaining that there has been progressive failure of vision in the left eye. As this is the eye in which the capsule was left undisturbed, I immediately suspect that changes in that membrane, either partial opacity or wrinkling, are the cause of the progressive loss of vision. Certainly in a large majority of cases, if not in all, there occur within a year or two after the extraction of the lens secondary changes in the remaining portion of its capsule that unfit it for the proper transmission of light, and render some secondary operation necessary in order that the patient may enjoy the best possible vision.

Upon examination by oblique illumination and with the ophthalmoscope we find the capsule wrinkled and partially opaque in each eye. But in the right there is a triangular opening in this membrane through which the patient sees clearly. In many of these cases although very little opacity is to be found the wrinkling alone, by the irregular astigmatism that it causes, constitutes a complete bar to good vision, and that is just the condition of this case.

I shall now attempt to make a sufficient opening in this wrinkled capsule to allow of good vision through it. Such an opening does not have to be very large, yet it is often quite difficult to secure it on account of the extreme elasticity of the membrane with which we have to deal. In order to get as free movement as possible for the cutting edge of the needle, the entrance is made at the extreme periphery of the cornea. At this part the needle is necessarily fixed and the farther away the point of cutting the capsule from this fixed point the freer the movement of the cutting edge. Sometimes to get still freer movement it is well to introduce the needle through the sclerotic, back of the ciliary region, and make the cut in the membrane from behind.

In this case I introduce the knife-needle at the periphery of the clear cornea on the temporal side, pierce the membrane near the lower nasal margin of the pupil and make the incision thence to the lower temporal border. Then the knife is withdrawn sufficiently to bring its point in front of the membrane and it is made to transfix it at the upper margin of the pupil and cut downward. In this way a T-shaped incision is secured, which is dilated by protruding viterous into a sufficiently large clear pupil.

For the after treatment of this case, duboisin sulphate is to be instilled twice a day until the eye is quite free from redness. For the first few hours he will have the eye covered with a little absorbent cotton and this muslin shade which we call here a "Liebreich bandage," although it is entirely different from the knitted bandage described by that London surgeon. This closing of the eye is merely to exclude external contamination, until the little corneal wound is quite closed, which will be in a very few hours. After that he will wear dark glases until the effect of the duboisin has passed off, and before he leaves the hospital we will carefully test his refraction again. Not because it is likely to be changed by this operation, but to see if it has changed materially since shortly after the primary operation when his glasses were adjusted.

Drunk or Dying.

The uncertainty of diagnosis in head injuries has once more been illustrated by a case that recently occurred at the San Francisco Receiving Hospital (*Occ. Med. Times*). On September 3, 1892, M. C. Shaw, aged 37, a civil engineer by profession, was knocked down by a cable car. He was dazed by the blow, but seemed to recover consciousness in a few minutes. The patrol was summoned, and, though he protested he was not hurt, and wanted to go home, his friends thought best to bring him to the hospital. The assistant surgeon on duty found several abrasions and contusions about the forehead, but no certain signs of serious injury. The patient, however, presented apparent symptoms of intoxication. He had walked into the hospital with a slightly unsteady gait, talked a great deal, declaring that it was nonsense to dress the abrasions on his head, took money from his pockets to pay the surgeon and steward for their trouble, and in many ways acted as an intoxicated person would. From the nature of the accident, however, the surgeon suspected that there might be internal injuries, and accordingly entered the diagnosis on the books as "doubtful." The man was placed in the hospital ward and kept for observation. He appeared to fall asleep at once, but never awoke. Six hours after entering he died. A post-mortem examination showed fracture at the base of the skull, in the occipital bone. The external injuries were all in the fore part of the head, and as the occipital region showed no wound, the fracture was evidently from contre coup.

"Who makes the kittens, Jackie?" "Why, God makes them, Ethel. He doesn't make them as He does babies, one by one, but He just says, 'Let there be kittens,' and there are kittens."

COMMUNICATIONS.

HYPODERMATIC MEDICATION IN SYPHILIS.*

L. WOLFF, M. D., PHILADELPHIA.†

Amongst the therapeutic methods which are largely employed on the continent of Europe, but have found very few adherents in this country is, no doubt, the hypodermatic treatment of syphilis. Although proposed and practiced in the early part of 1860, it was some time before it was extensively employed even abroad. This was, no doubt, largely due to the fact that it was little understood, that, from temerity, the doses employed were by far too small, and results, therefore, not brilliant, as well as from fear of the formation of abscesses and the necessary amount of pain accompanying such medication. The pain accompanying it is today still an argument against its employment that is not to be overcome. If we, however, consider that in the principal medical centres of continental Europe little or almost no mercury is given internally any more, even the pain accompanying and following the injections must be outweighed by the results. While the first experiments on hypodermatic medication in syphilis were made with solutions of corrosive sublimate, the insoluble mercurials were soon substituted by Scarenzio and others. Therefore, we may divide the mercurials into those preparations which are soluble and those which are insoluble mercurials. It was found that if insoluble mercurials were introduced beneath the skin they were rapidly absorbed, that they were soon found in the urine, and, also, often produced the untoward effects of mercury, besides their characteristic inhibiting and curative influence over the lesions of syphilis.

In a former paper on this subject (*Therapeutic Gazette,* November 15, 1889) I dwelt on the history of this method of medication and gave, also, a synopsis of the literature on the subject. I shall, therefore, in this paper, consider principally my experience with this treatment and with the various agents so employed. During my student days I had the opportunity of watching and practising this method, and I have continued to employ it to this day in a large and varied practise which has brought, perhaps, to me an unusual number of cases of early and secondary syphilis. Though I have again and again abandoned it, owing to the pain it occasioned, I have always had to revert to it in order to satisfy my patients, who, if they had been treated hypodermically once, and were then treated with mercurials taken by the mouth, would gladly stand the pain of the injections rather than the slow results and the digestive derangement caused by the older methods of medication.

I usually begin the injections of corrosive sublimate in the intra-scapular region on one side and about two inches from the posterior vertebral processes, and continue down the back in the costal interspaces—the injections being about one or one and a half inches apart. The effect of the injections on still open primary sores, on indurated glands, on macular syphilides, and on pharyngeal ulcerations may be said to be almost magical. It is noticeable that within a few days, and usually within one week or ten days, all these signs have disappeared. The same beneficent results may, also, be said to take place in specific iritis and choroiditis, and it is especially in these two affections that I consider the hypodermatic administration of corrosive sublimate, in the doses and manner mentioned, of the greatest value. Papular eruptions do not show the same tendency to disappear rapidly under the hypodermatic treatment, but have usually faded within a few weeks. The effect on luetic fever and nocturnal pains is so marked that with the first or second injection the patient notices a marked improvement. I never use less than a one-fourth grain injection at one time and generally employ a one per cent.

*Read before Phila. Co. Med. Soc., March 8, 1893.

solution in distilled water, filling a syringe of twenty-five minims capacity. These injections are continued daily, and during the first week or two patients stand the treatment fairly well. There is rarely, during this period, any evidence of soreness of the mouth or gums, nor is there any intestinal trouble noticeable. After the entire back, on both sides, had been gone over with injections, many of which have left quite sensitive indurations, their repetition in or near the old places prove quite painful, and it is only then that real complaints from patients are heard. Usually after eighteen or twenty injections tumefaction of the gums becomes marked, and gingivitis is often noticed. The daily injections are then intermitted, and are made at intervals of two, three or four days, the untoward symptoms rapidly disappearing during such intervals. The total number of injections usually made in any one treatment is about twenty-five, but I have continued them to the number of thirty or thirty-five, when marked pigmentation of the local lesions supervened. A good rule may be to carry on hyper-medication for about two weeks after the total disappearance of all symptoms. It is, of course, understood that during this time the patient is to be supported by a liberal diet, by milk punches, and, when the digestion is impaired, by tonics and quinine. The mouth should be kept scrupulously clean, the teeth being cleansed after each meal and at bedtime with a soft brush dipped in a solution of one drachm of potassium chlorate to six ounces of water, and containing, also, a drop of carbolic acid to each fluid ounce. While warm full baths or steam and hot-air baths are adjuvants to the treatment, the cold bath should be interdicted as well as exposure to cold and deprivations. I may safely say that I have made thousands of these injections, and have yet to record a case where they have been followed by abscess or sloughing. All of my cases so treated were ambulant, and I do not remember that any of them have lost a day from their usual vocations.

The immediate effects of the corrosive sublimate have been so uniformly good that I need to consider now only the remote effects on the progress of the disease and its liability to relapses. The permanency of a remedy in syphilis is one of the features of the greatest importance, and here I must say that as rapid as is the beneficial effect of this method of medication, there is a corresponding large number of relapses. Of the cases that I have so treated, and of which I have been able to keep a record, I can safely state that in about 60 per cent. no further symptoms developed. I have notes on a number who subsequently married and raised apparently healthy offspring. Of the remaining 40 per cent., however, I cannot say that they have done so well, and many of them after receiving two, three, and even four courses of treatment by injection had to submit to treatment by systematic inuction before the tendency to relapse has been overcome.

It is this tendency to relapses which has caused me to abandon hypodermatic injections after a second failure as to permanency of cure. It made me investigate the many other mercurials suitable for hypodermatic medication. It has been experimentally proven by Vajda, of Vienna ("Ueber den Einfluss des Queck-silbers auf den syphilitischen process"), that the iodides inhibited the elimination of mercury by the kidneys, and that the slower the elimination the greater the safety from relapses. For this reason it has been my practice to give from five to ten grains of potassium iodide three times daily, after the injection treatment, for months to come; but even this plan has not always prevented frequent relapses. Acting on this indication, and at the suggestion of my friend Dr. Thomas H. Fenton, I have tried injections of iodo-hydrargyrate of potassium, a compound of iodine and mercury, but I have found these injections no less painful, and their permanency has not been greater in my hands than with the corrosive sublimate treatment. In respect to permanency, it is said that the injections of the insoluble mercurials are of greater benefit than the soluble ones. This might be inferred from the fact that their conversion into a soluble compound beneath the skin is a slower process, and while thus a mild continued mercurialization is produced the injections need not be repeated so often. The insoluble mercurials have, however, the disadvantage of not being always aseptic, nor of being readily rendered so. It is true that with the introduction of vaseline oil as a vehicle for their hypo-

dermatic administration they can be rendered both less septic as well as less painful.

At the head of the insoluble preparations, so far as efficiency is concerned, calomel must figure. I give below the formula for its use, as well as the formulæ for other of the insoluble mercurials, according to Professor Edward Lang in his "Ordinations Formeln:"

℞ Calomel } .....āa 4.5 grammes.
Vaseline oil }
Lanolin..... 4 "

Each c.cm. contains 0.371 grammes of mercury, 0.1 c.cm. to be injected not oftener than two or three times the first week.

The precipitated mercuric oxide (hydrarg. oxid. flav.) comes next.

℞ Yellow oxide of mercury..... 4 grammes.
Vaseline oil..... 4.5 "
Lanolin..... 3.5 "

Each c.cm. contains 0.391 grammes of mercury. To be used as the calomel injection.

The salicylate of mercury is lauded very highly, and is prepared for injection as follows:

℞ Salicylate of mercury..... 7 grammes.
Vaseline oil..... 4 "
Lanolin..... 2 "

Each c cm. contains 0.391 grammes of mercury.

The latest preparation and, at the present time, the one generally employed in the hospitals of Paris, even by the veteran Fournier, is the mercurous oxide, which is really a mercurous-mercuric oxide, but better known as the black oxide of mercury. It is used as per following formula:

℞ Black oxide of mercury..... 4.7 grammes.
Vaseline oil..... 6.2 "
Lanolin..... 3.1 "

Each c.cm. containing 0.39 grammes of mercury, and to be used as the other preparations.

I might go on and quote in the same manner the thymol-acetate, the diphenylate, and the sozoiodolate of mercury and other forms of the drug, but, as those named are the preparations generally used, I will omit the others.

It will appear from the above that, after all, the virtues of the preparations quoted consist in the amount of mercury they contain and in the slowness of its conversion beneath the skin. The more rapidly converted the sooner the lesions disappear, the more mercury introduced with safety to the general health the greater the curative effect on syphilis; but the slower and more persistent the conversion the greater the permanency of the treatment and the likelihood of a total extinction of the syphilitic poison. It may be said against these insoluble mercurials, and with some force, that their advantage over the soluble preparations is only by their slower action, while the marked local reaction which they produce is quite as much as with the soluble mercurials. Such is really the case, and the desideratum, therefore, seems to be to employ a preparation that will produce the least reaction and that will be slowly converted, while least in its probability to produce untoward effects. Professor Edward Lang, of Vienna, some years ago experimented on the direct introduction of metallic mercury in minute subdivision as being nearest to the ideal method of inunctions, which yet hold the highest place in permanency in the treatment of syphilis. He found that they were readily borne, that they produced little or no local reaction, and, an acconnt of the slow conversion of the mercury, needed repetition only at long intervals. He claimed that the introduction of the metalic mercury hypodermically exercised an influence over the syphilitic process which was in direct proportion to its conversion, which could be studied by its excretion through the kidneys. This appealed to me as one of the methods most likely to prove more permanent than any of the others, and I introduced it in my private practice as well as in the wards of the German Hospital under my control.

To fully describe this method I must mention the manner of its preparation for hypodermic use, as given by Professor Lang in his "Ordinations Formeln." This consists in first making an ointment of mercury with lanolin, as follows:

Anhydric lanolin, 15 grammes; dissolve in q. s. chloroform 50 grammes, and evaporate the cloroform by continued stirring until the weight is 30 grammes, then add pure metallic mercury, 30 grammes, and continue stirring until all the chloroform is evaporated and the mercury is perfectly extinguished. (This can be recognized, if, by spreading with a spatula on paper, no mercury globules are visible by means of a magnifying glass).

This is his strong lanolin mercurial ointment, and it forms the basis for his oleum cinereum or gray oil. Of the latter he has two preparations, according to the dilutions, the 50 per cent. and the 30 per cent. oil. The formula for the former is as follows:

℞ Strong lanolin mercurial ointment..9 grammes.
Olive, almond, or vaseline oil..... 3 "
Mix well.

This contains in each 0.05 c.cm. to 0.04 c. cm. of mercury. 0.05 c.cm. is the average dose for injections, but if it is desirable to inject double the quantity it is best done in two different places. To produce a very active effect it is advisable to inject twice a week 0.05 c.cm. of this strong oil until all symptoms have disappeared. After that, and to prevent relapses, 0.05 c.cm. should be injected about once a week or once in two weeks for some time afterward. All injections should be made, beneath the skin, in the back, about one inch from the median line, the semi-solid mixture being previously warmed by immersion in hot water until it becomes fluid. Lang also makes use of injections of 0.05 c.cm., two to four times during the first week, and subsequently every week, and later every two weeks, the same amount. He also recommends a milder gray oil, made as follows from the strong lanolin mercurial ointment:

℞ Strong lanolin mercurial ointment 4.5 grammes.
Oil of sweet almonds (or olive oil or vaseline oil) ..... 5.5 "
M.

Each c.cm. of this contains 0.366 grammes of this mercury. This is termed the 30 per cent. gray oil. Of this oil one-tenth c.cm. is the average injection made in two places of the back.

These formulæ, complicated as they may seem, can be easily worked out, and when once the lanolin mercurial ointment is made the dilution requires very little time, as but small quantities are required; a half ounce will last for weeks and, if necessary, should be made fresh every month or two, although these oils really keep a much longer period.

The syringe for injections should be accurately gauged and sub-divided into 0.1 c.cm. and tenth parts thereof. The syringes, as made by Reiner, also Leiter, of Vienna, are used for that purpose, the total capacity of each being a half of a cubic centimetre. They have been accurately gauged, and a certificate of occuracy accompanies each. While it might be well to disinfect the needles and syringe before using, by syringing them with a 4 per cent. carbolic water, I have found that there is but little danger in private practice even if this precaution is not observed. The gluteal regions are said not to be very suitable for these injections.

In the use of the gray oil it has been my practice to inject 0.1 c.cm. every week for the first four to six weeks. Usually macular eruptions fade after the second or third injection, papular ones after the fourth or fifth. Examination of the urine showed the presence of mercury within the first week, and its presence was noted for a month and more after all injections had been stopped. The injections of smaller quantities (0.1 c.cm. of the 30 per cent. oil) in different parts of the back are of greater advantage than the injection of double the amount in one place, the urine showing the mercury sooner in the first case than in the second. The only precaution to be observed in the employment of the gray oil is not to use too much. It is a frequent temptation when the curative process is slow to increase the amount injected or to repeat it oftener. This is to be avoided, as the mercury is only slowly converted and accumulates to the point when it manifests its potency over the syphilitic process. Another precaution to be observed is to pay careful attention to the teeth and mouth. As the development of absorbable mercurial compounds is progressive the injections should be discontinued or made less, even upon the slightest effect noticed on the gums. This medication is a most effective and potent one, and I can readily see how, by lack of precaution, severe salivation might ensue. Let no one suppose that, as there is little reaction immediately upon the injection, it might be pushed without hesitation. The literature has several cases where an uncalled-for free use of this remedy has caused not only bad but also fatal results. In my experience such has not been the case, although I have employed it with uniformly happy results in a large number of cases.

To sum up the indications for the hypodermatic medication of syphilis, I should say that in cases where the symptoms require urgency of treatment I would employ the injection of a one-fourth grain of corrosive sublimate, at first daily and subsequently every other day until about twenty-five injections had been given. If, after this, all the symptoms have not entirely subsided (entire absence of all pigmentation) I should resort to injec-

tions of the 30 per cent. gray oil, 0.1 c.cm. in one or two places in the back once a week until six to eight injections have been made. If, after a shorter or longer period without medication, further manifestations of syphilis should appear, the same series of injections with gray oil should be made and thus continued until, after long lapses between treatment, no further return of the lesions appears. The injections of corrosive sublimate, as described, have the advantage of more rapid action, and will often suffice. I should always recommend their use at first as preferable to others, but when relapses occur the injections of gray oil are both less painful and promise greater immunity from subsequent relapses.

MOTOR DISTURBANCES IN THE DISEASES OF CHILDREN.

A. W. WILMARTH, M. D.†

In this brief paper I have endeavored to condense from the voluminous and scattered literature on nervous disease in children, a few practical points which may be of service in the diagnosis and prognosis of such cases, as we meet them in every day practice.

Gowers, Bramwell, Osler, Sachs, McNutt, Buzzard and others have written at length on this class of disease, and it is from their writings I have drawn largely the material for this paper, adding a little from my own experience among cases of juvenile nervous disease.

The most significant symptoms of irritative or destructive changes in the nervous system of the young, are disturbances of the muscular system as evidenced by paralysis or convulsions, in changes in the electric and so-called reflex reactions. Convulsion is perhaps the most frequent form of expression of nervous irritability. It varies greatly in frequency and form. As the protest of the nervous system against an irritation, seemingly beyond its power of endurance, from the teasing irritation of an erupting tooth in the dentition of infancy, or the poison of one of the specific fevers, we are accustomed to see spasm result and are not liable to be greatly alarmed by its occurrence. When the immediate cause of irritation has seemingly disappeared and the occasional spasm still re-occurs at longer or shorter intervals, the questions at once confront us: When and what is the cause of this trouble? What is the probability of ultimate recovery?

That well-marked epileptic spasm, continuing for a considerable period, may occasionally result from continued peripheral irritation, such as optical defects, nasal polypi, etc., to disappear with the removal of the local cause, seems to be proved by abundant clinical testimony. That they arise from such causes nearly so often as some specialists would have us believe, may well be doubted. But such causes are operative so often that we should never fail to look for them, if possible, before falling back on the habitual use of bromides or other routine treatment. Such spasms may be expected to be general in character, and may coincide with increased pain or irritation in the diseased parts.

There is nothing in the ordinary general convulsion to require more than passing notice, but in the period of their occurrence and in the location of the so-called Jacksonian epilepsy, there is valuable information to be gained. In a recent publication I have given reasons in full for believing that when in epilepsy, aside from exciting causes of a temporary nature, convulsions show a tendency to return at regular intervals—say every 4th, 10th, or 14th day, or other definite period, —there is generally, in fact almost invariably, a definite organic lesion of the brain whose constant irritation finds expression through these regular explosions of nerve force. Permanent recovery in such cases can rarely be looked for.

Cases of Jacksonian epilepsy form an interesting study, for in them we can definitely locate the seat of irritation and enable the surgeon in suitable cases to cut down and remove the cause of mischief. Without going into detail, in this interest-

†Assistant Physician Norristown Hospital for the Insane.

ing form of spasmodic trouble, I will cite one typical case.

L. D., aged 16, walked into the office one day from his room near by, dazed and frightened, but able to find his way along. All the muscles on the right side of his face supplied by the seventh nerve were in a condition of rapid, clonic spasm. No other muscles were implicated. After about a minute's time this ceased, and the heavy breathing and tendency to sleep followed as in ordinary general convulsion, but not to the same degree. Occasionally, in this boy, the convulsion becomes severe and general, but always originates in this group of muscles. This case in its earlier stages would probably have been benefitted by operation; but now mental decadence indicates diffused cerebral changes.

The minor form of epilepsy, *petit mal*, is multiform in its phenomena and grave in its significance. It is generally indicative of beginning change in the intracranial organs, and unless early and vigorous treatment is begun, this will almost surely end in mental failure. It is liable to be overlooked in children; or if noticed, to escape treatment on account of its apparent insignificance. When met, it is not to be cured by "worm powders," though the family be ever so sure that these parasites are present; nor yet checked by large doses of bromides, for the attacks of themselves do little harm and may be our only indication of cerebral trouble; but every medical and hygienic measure should be employed to build up the brain to resist the destructive process that threatens it. I have notes of one case of a rare form of this disorder.

Chas. D., born 1880; father and mother both drunkards; the latter subject to violent fits of rage during this pregnancy, and below average intelligence. Child is strong, well formed, but mute. An unexpected light touch on the top of his head and he will fall to the ground as if struck down with a club. Rises immediately, looking pale and dazed, and regains full consciousness at once. If he sees your intention before he is touched, no effect follows. Hughlings Jackson describes one similar case. I have seen no others recorded. This peculiarity disappeared in time and well marked Jacksonian epilepsy followed.

One more clinical picture of convulsion will, perhaps, be of interest.

A child is found in a long series of convulsions, more generally of the Jacksonian type. Mild fever; convulsions usually short and not severe; period of unconciousness bridging the intervals between the spasms. These may last several hours, but more frequently a day or two, when, if the child does not die of exhaustion, some recovery takes place. I say *some* recovery, for the evidences of intra-cranial mischief are very apparent. If paralysis results, it will be complete and permanent. If the motor region escapes and other portions of the brain are attacked, the sensory or mental loss will be equally apparent. This is the effect of the so-called tuberous or hypertrophic sclerosis.

Convulsive attacks during the eruptive fevers may stimulate this condition, but they are of shorter duration, the spasm more severe, the stupor more profound, and the prognosis far more hopeful. I have used the term "Jacksonian epilepsy" in rather a broad sense. It is generally asserted that in this type consciousness is retained, but in nearly 400 cases of epilepsy of which I have had the care, I have yet to see a case in which consciousness was not in some degree, however slightly, affected.

Another frequent symptom of interference with functional activity or of actual organic change in the nervous system, is paralysis. This may exist at birth or may develop at any later period, and by its method of development in conjunction with other evidence of imperfect action in the nervous mechanism, may throw considerable light on the location and sometimes on the nature of the lesion of which it is a symptom. Paralysis at birth may be due to non-development, to intrauterine disease or to injury during delivery. An easy birth would exclude the latter cause.

Correct diagnosis is of importance in our judgment of the future of the case, for while Gowers asserts that in nearly all cases of birth palsy, when absolute idiocy does not result, some improvement follows. I am certain when the cause, be it disease or non-development, antedates delivery, marked improvement *rarely* occurs. In these cases, paralysis of non-development are usually of the flaccid variety. While more or less rigidity and generally complicating epilepsy, marks early sclerotic change resulting from fœtal or early infantile disease. One point should never

be lost sight of in any case where serious disease or injury has occurred in the upper brain in early infancy. That is, that mental development will very generally be checked or destroyed, and feeble-mindedness result. We have only to remember that competent judges place the number of this short-lived class, in this State alone, at nearly 9000, to realize how many minds are ruined by infantile disease each year.

The causes, nature and locality of the lesion in the paralysis of early childhood are better understood than in the congenital types. The more usual forms are commonly traced to one of three causes: 1, Result of infectious disease. 2, Anterior poliomyelitis or acute infantile spinal paralysis. 3, Cerebral lesion.

The first variety is often seen as a complication or sequel of diphtheria; or less often, of typhoid fever or pneumonia. It may appear in malarial fever. It is generally looked upon as the result on the peripheral nerves of the specific poison, and is the least grave of the three general forms. Its diagnosis is usually made clear by the accompanying symptoms.

Where paralysis results from disease of the nerve cells of the anterior horn of the spinal cord (constituting acute infantile spinal paralysis), it is heralded by considerable fever, rarely with convulsions, and may involve the muscular system quite extensively. The paralysis very rapidly reaches its highest degree, is followed by rapid wasting of the muscles, affection of the reflexes and diminution of faradic excitability. Bramwell states that fibrillary twitchings are often seen in these cases. It is often paraplegic, sometimes monoplegic, very rarely hemiplegic. Cerebral paralysis, on the contrary, is generally ushered in by convulsions, is most frequently hemiplegic. The most positive diagnostic test as to where the paralysis originates, is by the use of the galvanic and faradic currents. In anterior poliomyelitis, the excitability of the muscle to the faradic current soon disappears, and the slow but strong response to the galvanic current, known as the reaction of degeneration (R. D.), develops. Dr. Buzzard states that the faradic excitability may disappear entirely within a week, and the principle diagnostic sign of R. D. develop. This reaction does not exist in true cerebral palsy. Authors lay great stress on this symptom, not only for its diagnostic value, but also for its significance in prognosis. Miller and Duchenne state that muscles in which faradic excitability has entirely disappeared in four or five days, are permanently paralyzed. In those in which some excitability remains after the tenth or twelfth day, motility may be expected to return even though some months may be required. Buzzard entertains an even more hopeful view, especially when the loss of faradic excitability is slow. The loss of galvanic excitability is of grave import. Bartholow sums up these reactions as follows: When a child having one or more members paralyzed as a consequence of an anterior poliomyelitis is brought to you for treatment, you may promise much if the muscles react to the faradic current, however slightly. Be reserved if they react only to the galvanic current. Promise nothing when neither current causes the least movement. Paralysis may be present in spinal pachy-meningitis. Pain on movement and anæsthesia will help clear the diagnosis in such cases.

I think those few diagnostic points would be sufficient in most cases to distinguish the seat of origin of juvenile paralysis and so to select its treatment. In giving our opinion of the outcome of a case we should not forget that the age of onset has an important bearing in cerebral palsies. Osler states that the younger the child, the greater the liability to serious and permanent damage. The reverse holds true in epilepsy.

On the subject of the reflexes, we will consider at length only two, the patella reflex and the ankle clonus, and in dealing with them will quote some conclusions from the writings of Drs. Remak and Ziehen. In testing these reflexes in children we should exclude post-febrile paralysis and recent convulsions, both of which may decidedly influence them.

Unilateral exaggeration of patella reflex is always significant of disease. Bilateral is only significant when ankle clonus co-exists.

Ankle clonus may be physiological in children. Diminished plantar reflex with exaggerated knee jerk signifies functional and not organic disease.

Ankle clonus has the same relation to the lateral columns as Westphal's symptom has to the posterior columns. In

ordinary apoplexy with loss of consciousness, a primary foot clonus develops, which shortly disappears. If, in from two weeks to two months, ankle clonus reappears in the paralyzed limb it means secondary degeneration of the lateral columns and a certain anticipation of permanent contracture.

Unilateral ankle clonus in hemiplegia indicates a central lesion and almost always excludes a spinal affection.

The maintenance of patella reflex in spite of partial R. D., occurs probably only in polio-myelitis anterior. (*a*) The loss of patella reflex generally follows all cases of severe paralysis with relaxation of muscles, and diminished irritability of the nerves, whether of spinal or peripheral origin, and in case of recovery, this lasts longer than R. D. (*b*) Patella reflex fails in peripheral neuritis of mixed nerves. (*c*) Also fails in complete peripheral paralysis when there is no R. D.

In conclusion, I would say that in all cases where patella reflex fails in children, we should never fail to examine the spine in the dorsal and lumbar regions for evidence of Pott's disease with secondary inplication of the cord.

THE PRESENT STATUS OF CORROSIVE SUBLIMATE IN SURGERY.*

AP. MORGAN VANCE, M. D., Louisville, Ky.

I want to say a few words on a subject in which we are all inte rested—the present status of corrosive sublimate in surgery. For a long time all of us who work in general surgery have wondered why we failed to get good results in cases where we thought we had done everything that could be done to assure an antiseptic condition of the part. Two years ago I ceased the use of solutions particularly in fresh wounds, and have lately ceased to use them at all, even in suppurating conditions. Three years ago Welch, of the Johns-Hopkins University, made a report in which he mentioned numerous experiments with sublimate to find out something about the action and power of this drug. He has given us reasons why we often times fail in getting an aseptic condition or have an aseptic outcome of a wound from the use of this substance. It has been proven that the inhibiting power of bichloride of mercury is just so much, which is in proportion to the albuminous material it has to deal with. I think it is proven beyond all doubt by his experiments and by those of his assistants, particularly Abbott, that the present position of bichloride is rather against its use, and that it does more harm than good. If the solution be of sufficient strength to have any effect upon germs already there, it will cause necrosis and prevent healing of the wound, as well as producing a better nidus for the production and operation of other micro-organisms.

I will read from Dr. Abbott's paper, his conclusions upon this subject which may be of interest:

"What conclusions are we justified in drawing from such results as those obtained in the experiments here reported?

(1), It is seen that under the most favorable conditions a given amount of sublimate has the property of rendering inert only a certain number of individual organisms. That is to say the process is a definite chemical one taking place between the protoplasm of the individual bacteria and the sublimate in solution.

(2), That the disinfecting activity of the sublimate against organisms is profoundly influenced by the proportion of albuminous material contained in the medium in which the bacteria are present.

(3), That the relation between the golden pyogenic staphylococci and sublimate is not a constant one, organisms

* Read before the Medico-Chirurgical Society of Louisville, Feb. 17th, 1893.

from different sources and of different ages behaving differently when exposed to the same amount of the disinfectant for the same length of time.

(4), That the organisms which survive the exposure to the sublimate may experience a temporary attenuation. This attenuation, however, may be caused to disappear by successive cultivation in normal media.

(5), That by the method employed in these experiments, it is possible to select from a culture the most resistant forms in that culture.

(6), That many of the results of previous experimenters, who have assigned to corrosive sublimate more powerful disinfectant properties against the staphylococcus pyogenes aureus in cultures than the observations reported in this paper indicate, are attributable to the neglect of certain precautions now recognized as essential to the proper conduct of such experiments."

"In the light of these experiments and those of the experimenters quoted in this paper, it is plain that for use in surgical practice the solutions of corrosive sublimate do not possess all the advantages hitherto attributed to them.

"To the employment of sublimate solutions upon wound-surfaces it is plain that there exist at least two serious objections:

First, the albumen of the tissues and fluids of the body tends to diminish the strength of, or indeed renders entirely inert the solution employed.

And second, the integrity of the tissues is materially injured by the application of solutions of this salt."

"The first objection cannot be met with certainty, for the surgeon possesses no means by which he can determine the albuminous material with which his solutions are to come in contact, and in any case this large amount of albuminous material is an almost insuperable obstacle to complete disinfection with sublimate. He is, therefore, never in a position to say, *a priori*, that his efforts at disinfection of the wound are, or are not, successful."

"The second objection is equally serious. During the past two years we have had sufficient evidence to lead us to believe that the normal tissues and fluids of the body possess the power of rendering inert many kinds of organisms which may have gained access to them. This function is, therefore, diminished, or, indeed, may be quite destroyed, by any agent which brings about alterations in the constitution of these tissues. We know that just such changes as those to which we refer, are known to follow the application of sublimate solutions. It is plain that if we bring about in these tissues a condition of superficial necrosis—the condition following upon the application of sublimate—they are much less able to resist the inroads of infectious organisms than they would have been had they been left in their natural condition."

"As a disinfectant in the strict sense of the word, there are perhaps few substances which possess the property in a higher degree than does corrosive sublimate, but at the same time there is nothing which is employed for this purpose, that requires greater care in its manipulation in order to obtain its best results, than does this salt. As we have seen, its action is influenced by a number of conditions which in practical application it is difficult if not quite impossible, to control."

"For these reasons we seem hardly justified in continuing to give to it the first place in the list of substances which may be employed practically for the purpose of rendering harmless, materials containing the germs of infectious maladies."

I have found in my practical work. that since I ceased the use of sublimate solutions I have had much more uniformly good results by using simply sterilized water.

A case of failure of orificial methods has been reported in the *Jour. of Orificial Sur.* for November. A man was afflicted with impotency (variety and supposed cause not given). "All-round orificial work was done, including the American operation, circumcision, and removal of a portion of the scrotum; yet after a year no relief is reported." Why portions of the penis, testicle and vas deferens were not removed, is not stated.

A Dressing for Cuts, Sores, Scalds, Etc., Is made by boiling together 1 pound of resin and 3 ounces of clarified beef suet; then add 2 ounces of beeswax, boil one-half hour longer and allow to cool.—*Ex.*

IMPROVISED SPLINTS FOR FRACTURED LIMBS IN CASES OF EMERGENCY.

A. O. SIMPSON, M. D., Thompson, Pa.

In spite of the rapid strides that surgical science has made in our day and the great improvements in the art of treatment, emergencies do arise that tax the mechanical ingenuity of the surgeon to cope with. As an illustration in point I will cite a couple of cases:

I. On the 15th of July, 1888, while returning home from a neighboring town, I was stopped on the road and told that a Hungarian had broken his leg while wrestling. On going into the house I found a muscular railroad workingman lying on the bed with a broken leg. Both bones were broken about three inches above the ankle, the fracture being an oblique one and simple. I could not find any pasteboard in the house nor had I any splints or apparatus with me. I did however, have in my medicine case a small roller bandage and some adhesive plaster and chloroform. I administered a small quantity of chloroform; adjusted the broken bones; placed four strips about five inches long and one inch wide longitudually over seat of fracture; wound a strip of adhesive plaster spirally around the leg, over the longitudinal strips; over that I wound about two yards of muslin bandage, fastened it with needle and thread; placed the broken limb on a soft pillow, and then went in quest of a splint. Not far from the house I had seen some small second growth maple trees. I took a sharp ax with me, selected a tree of about the size of the lower part of the leg, girdled the tree and removed the bark from it in a section about ten inches in length. Then I went back to the house, tore up a piece of an old bed quilt, padded my splint and, after trimming it to proper shape with my knife, adjusted it to the limb and confined it there with three strips of bandage tied around and over the splint.

I did not see the man again for several days, but told him and his fellow workmen not to attempt to use the limb or to disturb the splint or bandages without my knowledge. Three or four days afterward I saw him and removed the splint and bandages. The ends of the bones were perfectly adjusted, and the cotton batting and improvised splint had moulded themselves to the shape of the limb. I reapplied the apparatus and told them to let the splints and bandages remain on for three weeks more, but that he might walk around the house with the aid of a crutch. At the end of the fourth week after the accident he discarded the splint and crutch and went to work again, using a cane to walk to and fro, as the leg was a little lame and stiff for about a week more. At the end of the fifth week there was no stiffness or lameness in the limb and the patient was perfectly sound.

II. R. T. (a blacksmith by occupation), on the 29th of June, 1892, while assisting in raising new bents on a barn, lost his balance, fell and fractured his leg near the ankle; from the fact of striking "terra firma" on his feet he fractured both bones. As he fell about twenty feet there was a compound fracture. I went to see him in the night but did not take any splints with me. Remembering my recent experience with the Hungarian, I did not feel in the least disturbed. I adjusted the fractured bones without chloroform, but using adhesive plaster, to retain fractured bones in apposition. Then I went into the woods near by and peeled a maple tree of proper size as in the previous case; trimmed off sharp corners of the bark splint with my knife; adjusted the splint to the limb with cotton batting; wound a muslin bandage over the splint with moderate tightness and strung up the limb by means of an iron pulley wheel screwed into the ceiling over his bed. By means of a cord attached to bandages around the limb and passed over the iron pulley, he could change the position of the limb "ad libitum." The well-padded maple bark splint proved a valuable mechanical and antiseptic appliance, as no change was ever made afterwards.

At the end of five weeks the splints were removed altogether. One week after the accident he was allowed to walk around the house with the aid of a crutch.

In neither of the cases mentioned here were any dry or moist applications used. From my own experience in such cases I have come to the conclusion that nature will do more toward the process of repair in case of fractured bones than art can do. All that the surgeon can do in such cases is to favor the effort of nature toward repair, by retaining the broken ends of bones in apposition.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCETY

Meeting of March 8th, 1893.

DISCUSSION.

Dr. Wolff's paper on Hypodermatic Medication in Syphilis. (See page 525.)

Dr. J. William White: There are some points in the paper which attracted my attention, although I make mention of them chiefly to disagree. The reader stated in one of the opening paragraphs of his paper that in the principal medical centres of Europe little or no mercury was given by the mouth, the inference being that in this respect we are behind the times. As a matter of fact, if we look over the present treatment of syphilis in the hands of the most distinguished men of the profession who have made syphilis a specialty, we shall see that the reverse of this statement is true, and that comparatively little is given hypodermatically. In Germany some of the best men have pronounced against it as the method of choice, although there it prevailed to a great extent. In France even the veteran Fournier has pronounced against the routine use of the hypodermatic method. In Great Britian, Jonathan Hutchinson finds no reason in his experience for the use of this method. In this country, Taylor and Keys, of New York; Bryson, of St. Louis, and specialists in all parts of the country are reserving the employment of this method for rare cases. I would, therefore, take issue with the statement that in the principal medical centres of Europe this is the method of choice.

Another point which attracted my attention was the extraordinary quality that his patients seem to possess of preferring this method of treatment. This is absolutely the reverse of the experience of everybody else who has put himself on record. Fournier has called attention to the fact that while you may cause a rapid disappearance of the disease, you also cause a rapid disappearance of the patient. Every French syphilographer, who has recently written, has emphasized this point with the exception of two or three enthusiasts who are still carrying on experiments in this direction.

The remarks in regard to the effect of the treatment on open sores, would seem to indicate that Dr. Wolff began the treatment very early. If the rule, not to begin treatment until constitutional symptoms are manifested, were adopted, it might change his percentages. His statistics are open to the imputation that the cases were not all cases of syphilis, on account of the fact that there is a considerable proportion of "sore" which it is impossible to diagnose, unless constitutional symptoms are waited for.

Dr. Wolff gives twenty-five to thirty injections, and then stops the treatment. That seems the most defective feature in the method. It has been claimed that the disease is cured by thirty-five injections, each of a quarter of a grain of corrosive sublimate, the treatment lasting a little over a month, a little less than nine grains of mercury being given. If this is true, we have to suppose that there is some virtue about mercury given in this way which it does not possess when administered in other ways. The evidence is steadily accumulating that it does not produce permanent cures and that it is attended by a larger number of relapses than other methods, and the claim that thirty or forty injections of a soluble preparation of mercury or five or six of an insoluble preparation will produce a

cure of syphilis, is without foundation. Dr. Wolff spoke of the liability to relapse, and I can readily understand this if he stops at the end of the thirty-five injections. If he had only forty per cent. of relapses, he was fortunate.

As to the insoluble preparation, calomel, which Dr. Wolff places first, is first in order of time, as it was introduced in 1864, and revived seven or ten years ago by Smirnoff, a Russian physician, and has, until a few years ago, kept its place. It has, however, been supplanted by the yellow oxide, which is now used more than any other insoluble preparation. The objection to this plan is that it is only another way of giving a soluble salt. The insoluble salt is slowly converted into a soluble form, and, so far as I understand the matter, this becomes one of the most inaccurate methods of giving mercury. One of the claims put forward for this method is that it insures scientific accuracy. Anything more unscientific, as regards precision of dose, than to throw under the skin an emulsion of metallic mercury in lanolin or a quantity of calomel or yellow oxide, and allow it to remain there, subject to the vicissitudes of different degrees of inflammatory action attended with different degrees of absorption, would be hard to imagine.

As to the freedom from harmful consequences, as a matter of fact you have in some patients, as a direct result of this treatment, a violent stomatitis, dangerous salivation, entero-colitis with bloody stools, and where vaseline or fatty preparations are used, pulmonary embolism. There are on record fatal cases from these sources. Occasionally the metallic mercury remains under the skin inert for a time, and then suddenly becomes absorbed in large quantities, with the development of violent symptoms.

These objections are founded upon the observations of men who were advocates of the method, and who have had the frankness to record their unfavorable cases, and cannot be disputed. Autopsis in cases where the insoluble salts have been administered experimentally in other diseases, show that there is great variability in the rapidity of absorption.

The pain is severe and belongs to every mercurial salt administered in this way. Lang's statement in regard to the absence of pain and other symptoms after the administration of the gray oil, is contradicted by other observers. In the best hands there has been a certain per centage of abscesses, and although the introduction of antiseptic methods has reduced their number, they are occasionally inevitable. Far more frequent are the painful nodosities about the seat of the injection.

The conditions under which the method should be employed are extremely limited. I believe that it should be held in reserve for cases where other methods have failed. Given a patient whose gastro-intestinal tract reacts to mercury in such a way that the various preparations become irritants, and in whom the use of inunctions produces a violent dermatitis or mercurial erythema, and such a case would suggest a trial of the hypodermatic method. In grave emergencies, such as the serious eye-troubles of the secondary stage, it might even be regarded upon an equal basis with inunctions. There is no evidence to show that it is of greater value. If you want to produce rapid mercurialization, the administration of small doses of the protiodide, calomel or mercury and chalk, supplemented by the simultaneous inunction of mercurial ointment, will almost equal in rapidity the use of the soluble salts of mercury. I think that everyone will admit that in the presence of threatened grave complications, the hypodermatic method might be suggested. In old syphilis, mercury does not take the place of iodide of potassium. If you have a gummatous meningitis, or an infiltrating gumma of the brain, or a periostitis in the late stages of syphilis, or if you have any of the tertiary phenomena, while mercury hypodermatically might be useful it should be regarded only as a valuable adjuvant, but secondary to the use of the iodide of potassium.

I think that this subject is well worth discussing, and I am extremely glad that Dr. Wolff has read this paper. I came to hear it, and to put myself on record in relation to the whole question. I think that in what I have said I have spoken the views of the majority of syphilographers.

Dr. Richard A. Cleeman: I have used the hypodermatic method, and I think that Dr. White is a little severe. I have had several patients who prefer it very much to mercury by the mouth. I

have used more than thirty-five consecutive injections, and have given as much as one-third of a grain at a time, giving two injections of one-sixth of a grain each. I have never had abscess, but I have seen the painful nodosities, and once I had to stop because the parts were so painful that the patient was not willing to continue the treatment. After the nodosities disappeared, he came back and the treatment was resumed.

I have found, contrary to what has been said in the books, that a small quantity of corrosive sublimate will not remove the symptoms, particularly in cases of tuberculous skin disease in the form complicated with ulceration. You have to use many injections before any effect on the ulceration is produced. Finally, the ulcerations disappear as a rule. The great advantage of the use of injections is that you overcome the great tediousness of the ordinary treatment and the liability of the production of digestive disturbances. In a case I have in mind the man was in splendid general health while the hypodermatic method was used, but when mercury was used by the mouth he suffered from diarrhœa and troubles with stomach.

I have not used injections in the primary stage of syphilis, but in one case I have used them immediately on the appearance of the secondary symptoms. After the use of twelve injections the symptoms disappeared, but they reappeared in the course of a month in a rather unusual form—that of thickening of the nails. I am now using injections in this case. The general health is excellent, although he was much run down before; he is much pleased with the method. The pain, while it is sometimes severe, is not unbearable.

Dr. J. A. Cantrell: Contrary to the experience of Dr. White, I must say that the hypodermatic treatment of syphilis will cure in most of the cases. I have seen forty or fifty cases where the treatment has been continued up to thirty or thirty-five injections, and where the patients have not come back for the treatment of the disease. I have seen one of these cases seven years after the treatment, and there had been no return of the disease. I have, however, seen cases where the injections have been continued until as many as sixty or even one hundred and twenty had been given without benefit. Fournier has, I believe, within a month injected for macular syphiloderm. Sometimes the injections are not absorbed for a week or ten days, and often leave decided ulceration. In the cases in which I have seen the method employed, I think it would have been better to have used internal treatment, and if the cases did not do well the hypodermatic method might have been tried.

Dr. Edwin Rosenthal: I have used the hypodermatic injections of corrosive sublimate quite a number of times. I think that Dr. White is too severe in his denunciation of this method of treating syphilis. Practical experience has demonstrated its utility and the many advantages it has over other methods. The inuction method for instance, is the dirtiest that can be employed, and will drive away more patients than the hypodermatic method will. One of the points in favor of the latter method is that the patient has nothing to do with the treatment, but eat and drink whilst undergoing a cure. The injections are cleanly, devoid of all risk when judiciously made; at first they are made daily, and afterward every second or third day.

I have given the injections in the primary disease, in a case of chancre of the tongue, in which the lymphatic glands in the cervical region were very much enlarged, and where the internal administration of remedies could not be borne by the patient, and prompt treatment was indicated, with very good results. This patient is still under treatment, but there has been no appearance of an eruption.

Speaking of the large dosage given at a single injection and its good results, I wish to record another point, and that is: In infantile syphilis the dose of $\frac{1}{200}$ or $\frac{1}{100}$ grain of corrosive sublimate, as recommended by Dr. Jacobi (*Journal of Pediætrics*), is too small. I have seen a vast number of cases of infantile syphilis, and have lost quite a number, until I increased my dosage; and I never begin with less than $\frac{1}{60}$ grain of corrosive sublimate, and gradually increase the dose.

Dr. Charles Wirgman: A point to be borne in mind, both in private and hospital practice, is that as soon as the lesions disappear the patient ceases to return for treatment. No matter how eloquent you may be in regard to the neces-

sity of continuing treatment, they disappear. If it could be demonstrated by a more extensive use of this method that 35, 75, or even 175 injections will take the place of two or three years' treatment, that would be a great boon to humanity, and the question is worthy of serious consideration and further trial.

Dr. S. Solis-Cohen: The discussion points to the fact that it would be well to elicit further testimony as to the time when a syphilitic patient can be considered "cured." My own experience has been so largely with late lesions, occurring in cases that have been treated by many different methods, and in which quite a number of years has elapsed since the primary infection, that I am compelled to consider it at least premature, because symptoms may have disappeared for a time, to say that the treatment has cured the disease. The patient must, it seems to me, be kept under observation for a prolonged period, before we can record even a probable cure or recovery; and this is the fatal defect of all methods which limit themselves to a comparatively brief period during the time of early symptoms. My personal use of hypodermatic injections of mercury in syphilis has been limited to the employment of corrosive sublimate for rapid effect in early or late cases, so that I am unable to discuss the other methods, except from a theoretical standpoint; and therein I am entirely in accord with Dr. White. In the extreme cases of late lesions I sometimes meet, I resort preferably to inunction, associated with or followed quickly by internal use of potassium iodide in ascending doses; and acting upon a suggestion of Bartholow's, I sometimes conjoin with this the steam bath and the hypodermatic use of pilocarpine, to hasten elimination. It is dangerous to push the action of tissue-destructives unless we provide for rapid elimination. Hence the advantage, too, of giving large draughts of water or milk with potassium iodide.

Dr. Joseph Hearn: I have used the hypodermatic method in only one case where the stomach was irritable Under treatment of one-eighth of a grain doses the patient improved. I think that it is a method which should be held in reserve. There are cases which cannot bear the iodides. I have been taught that the iodides do not cure syphilis, but rather its consequences. Only mercury cures syphilis. If I am in a hurry, I use inunctions, but if there is no urgency I use internal treatment. I cannot say how many of my cases are cured. I believe that the disease can be put in abeyance so that the patient will live any length of time.

I would like to ask if the administration of mercury during the primary stage will mask the secondary symptoms so that you cannot recognize them.

Dr. James Mitchell: We have patients with syphilis where the disease appears to have taken a mild form. I have used all forms of treatment with the exception of the hypodermatic. My experiences of late years has been principally with the secondary and tertiary affections, particularly of the eye. I find that sometimes the patient deny anything like infection. I think that when we come to a study of the treatment of any disease we must take into consideration the fact that all diseases vary in their intensity in different individuals. And I think that this is the reason that we have different results with the same treatment, and why one method of treatment will fail while another will effect a cure.

Dr. John B. Deaver: My experience with the hypodermatic administration of mercury is comparatively limited. I have not used it sufficiently to say much in its favor. Of course, one of the objections is the decided pain which it causes. Painful indurations have been marked in some cases and have been some time in disappearing. I have, however, seen most excellent results obtained in ulcerative conditions of the pharynx and soft palate, where the internal administration of mercury did not suffice, largely, perhaps, because it excited irritation of the digestive tract, and where inunction had also failed.

One of the weakest arguments against the use of injections is that a cure is produced in so short a time. I believe that many of the cases of early relapse are due to the fact that the physician has been led to believe that he has cured the case. From my observation, I think that treatment should be prolonged for four years, or, at least, three years. I have had sufficient satisfaction with the ordinary treatment not to resort to the hypodermatic method, except in special cases.

Dr. White: In reply to the question

of Dr. Hearn, I would say that I believe that the prompt administration of mercury in primary syphilis will prevent the appearance of the secondary symptoms. I used to think to the contrary, but observation, experience and reading have led me to change my views.

I know of no test which can be applied to the individual which will demonstrate the presence or absence of active syphilis. I believe that 90 to 95 per cent. of the cases can be cured, but it is impossible to say at the beginning which of the cases will not be cured. As a matter of fact, syphilis is inclined to be a self-limited disease. Nothing but the experience of years will demonstrate the possible cure. The point has already been made in regard to relapses, and I think that figures are accumulating that are distinctly against the method, and will show that the proportion of relapses with the hypodermatic method is greater than under the classical methods which we have been using.

Dr. Drake: I have recently returned from Europe. For six months I was Kapsoi's assistant. In most of his cases he uses the hypodermatic method, the injection being made in the gluteal region once a week. Neuman, of Vienna, uses the salicylate of mercury hypodermatically. He also uses internal treatment in some cases. Lang, of Vienna, is at the present time experimenting with the gray oil. Lukasiewicz also uses injections of a five per cent. corrosive sublimate solution, a gramme every week.

In Berlin, the dermatologists and syphilographers, Joseph and Lassar, use hypodermatic injections in most of their cases. In some, they use inunction.

In Paris, Fournier was using hypodermatic injections at the time that I left. In some cases there, after the first injection the eruption entirely disappeared. Of course, it was a little painful, but it did not occasion the patients much trouble, and they gladly submitted to the treatment, and preferred the hypodermatic injections.

Dr. Wolff: As stated in my paper, I have made thousands of injections, and the patients whom I have taken off the hypodermatic method and given protiodide by the mouth, have asked to have the former method resumed. They did not seem to mind the pain very much.

In regard to the administration of the remedy before the diagnosis was established, I would state that the injections were not made until the muscular eruptions and other characteristic symptoms had manifested themselves. I never treat constitutionally for the primary sore alone.

As to the results, I stated that I have found no return of the symptoms in sixty per cent. of the cases. I do not know whether or not these gentlemen can tell syphilis when there are no symptoms. Syphilis is only present, in my opinion, when there are symptoms. The duration of the treatment has been, on an average, twenty-five injections, and I am not the only one who makes that statement. Many thousands of cases have been treated at the Charitè in Berlin.

Kaposi led the discussion on the therapeutics for syphilis, at the Congress für innere Medizin in Wiesbaden, 1887, and it was generally accepted for the principal methods of treatment and the relative permanency of their results, as follows: the inunction method, most permanent; the calomel injection treatment next, and the hypodermatic injection of corrosive sublimate, as third. It was stated elsewhere that the permanent results of the first were 75 per cent.; the second 70 per cent.; the latter, 65 per cent. My results have not been so good, although I injected larger doses and for a longer time.

In regard to the time of cure. This may be said to be obtained when there is no return of symptoms. There is no such thing as saying that syphilis will be extinct after two or after four years. I have seen it return after twenty years, in spite of treatment. There is only extinction when there is no return of symptoms. To limit it to any one time is almost out of the question, because the time of cure for syphilis cannot be predicted.

I have given my paper as the result of personal experience. If mistakes have been made, they have been the result of misinterpretation and lack of a sufficient number of cases, rather than a want of truthful statement.

Post-partum Uterine Pains.—(Treatment.)

[Rutherford—*Rev. Gen. de Cl. et de Ther.*]

℞ Quinine Sulphate.....1.0 gms. [15 grs.]
Opium.....0.5 gms. [7½ grs.]
Buckbean Extract.....q. s.

Divide into 15 pills. One every 2–3 hours.

THE MEDICO-CHIRURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting February 17th, 1893.

Dr. F. C. Simpson, President, in the Chair.

ANEURISM OF CHEEK—OPERATION.

Dr. W. O. Roberts: This patient was before the society last summer and is a patient referred to me by Dr. Turner Anderson. You will doubtless remember the case as one of circumscribed aneurism resulting from injury to the face by a blow on the cheek with a stick. The aneurism had attained a considerable size and the tissues superficial to it were so very thin as to look as though about to burst. On September 8th I operated removing the tumor, and it was with great difficulty that I was able to dissect the skin from the sac of the aneurism. I finally succeeded, but failed however to get union by first intention throughout the whole surface. The girl left the infirmary in two weeks with the wound nearly healed. A week afterward, she noticed in eating that considerable watery fluid would run out of the wound. She came to see me and I found she had, as a result of the little sloughing that took place, a salivary fistula and this continued to discharge up to two or three weeks ago. The treatment was pressure until the wound grew very small, then it was dressed once or twice every day with collodion and iodoform—iodoform dissolved in collodion. Now the discharge has entirely ceased. I thought at one time that I would have to operate on the duct, but with the application of collodion and iodoform the wound entirely healed. There was never any salivary discharge until after suppuration occurred.

SUPPURATION OF PAROTID GLAND.

Dr. S. C. Dabney: I will report two cases of suppuration of the parotid gland, both of which I saw in consultation, the attending physicians thinking that disease of the ear existed. In the first case the first positive information that we had of suppuration of the parotid gland, was discharge of the abscess through its duct into the mouth. There was very considerable swelling, and it came on without any cause whatever that could be ascertained, neither mumps nor any acute disease having preceded. Diagnosis having been made of this trouble, I did not see that it was necessary for me to remain longer. The physician in charge made an incision letting out the pus, and the patient recovered without any further trouble.

No. 2. The second case was very much like the one just reported, except that the face was enormously swollen. She complained of no swelling in the throat, no pain, and no difficulty in swallowing. On looking into the mouth I discovered what appeared to be an immense quinzy, I thought this was very remarkable in view of the fact that there was no difficulty in swallowing and no well-marked pain referred to the throat. An opening was made in the abscess which was just above the left tonsil involving the pharynx and the soft palate. After the incision was made, a large quantity of pus was discharged. I did not see the patient again but was told by the physician in charge that a few days after opening the abscess in the throat, there was distinct evidence of pus on the outside of the face over the lower part of the parotid gland. An incision here gave exit to a large quantity of fetid pus. No communication could be traced from the external opening to that in the throat. The case is unusual, first, because of this external abscess accompanying a quinzy and secondly, because of the entire absence of the pain and difficulty of deglutition and of breathing which usually attend this disease.

DISCUSSION.

Dr. A. M. Vance: Was the gland proper involved or was it peri-adenitis ?

Dr. S. G. Dabney: It seems to me that it was most likely the gland itself from the situation of the swelling. All the symptoms of quinzy were absent so far as the throat was concerned, which seems to me the most remarkable feature of the case.

Dr. A. M. Vance: In connection with the trouble of the cheek, I would like to mention a case that I saw several

years ago, where a razor wound on a negro boy's face in healing evidently obstructed the duct. The external wound healed perfectly, and a large cyst occurred containing about a pint of fluid, the cyst probably destroying the outlet of the duct into the mouth. Dr. Godshaw referred the case to me and I endeavored to produce an opening into the mouth. I finally succeeded by using a slender canula such as is used in dropsy of the legs. I inserted one and let the boy wear it for a month, then removed it and the aperture closed up; I then inserted it again in the previously made opening. Whether it was near the normal one or not I cannot tell, but I finally succeeded in producing, by this small canula, a new duct—I believe it is possible to produce a new duct in this way. Of course I may have been fortunate enough to strike the natural one, simply re-opening it. The boy never had any more trouble after the second insertion.

Dr. W. O. Roberts: In the case reported by me, I thought at one time, as the wound was rather slow in healing, that I would have to carry the duct into the mouth, as is usually done in these cases, closing the external wound. But by the persistent use of collodion it has completely healed, as very frequently happens.

CANCER OF ŒSOPHAGUS; RUPTURE INTO THORACIC CAVITY; DEATH.

Dr. J. B. Marvin: This is a specimen I obtained from a case dying very suddenly at the Baptist Orphan's Home some weeks ago. The patient was a maiden lady about fifty years of age, brought here last summer to consult me, by Dr. Woolfolk, of Owensboro, with the statement that she had some trouble with the gullet, and that the home doctors were undecided whether it was spasmodic stricture, or whether there was an organic stricture, or whether there might be something else to account for the trouble. I left the city in August and turned the case over to Dr. Weidner, who treated her during my absence, the woman growing considerably better. She was one of those pale delicate women; never had been strong; suffered from severe attacks of asthma, etc. When I returned in October, she came back and I saw her at that time; she was able to eat fluids and some solids, and was in every way a great deal better. Dr. Weidner had concluded that it was purely a nervous stricture, spasmodic in character, and had washed the bowels out thoroughly, getting her in good condition, had given her massage, etc. She had quite an attack of trouble with her lungs at that time, and I differed from Dr. Weidner; he thought she had no pulmonary trouble, and I thought she had phthisis. I wrote to Dr. Woolfolk that I believed the result of treatment had proven the trouble was functional or spasmodic stricture of nervous origin. She went home, and after a time returned, looking not quite so well. She had more difficulty in swallowing; some days she could apparently swallow all right, then food would lodge and she would spit it up after a few hours. Bowels had been gotten in much better shape. She had a very unfavorable look, but I made no examination instructing her to resume the rubbing with whiskey and oil, and to take whiskey in small quantities internally. Two days afterward I was summoned very hurriedly, with the statement that she had not been so well the preceding days, had more cough and very free expectoration, and that day had gotten up and was moving about the house. She was eating her dinner when she remarked that she would go to her room on the next floor. About fifteen minutes afterwaad they found her dead on the floor. There had been an evacuation from the bowels and also from the mouth, of a very offensive muco-purulent looking material. I made the autopsy with Dr. Frank and exhibit here the specimens removed.

It was a cancer of the œsophagus which had ruptured into the thoracic cavity. I found in the thorax this little body, which is evidently a sugar coated pill; how long it had been there I do not know. The appearance of the lung indicates clearly that the trouble was not tubercular. Sections of the nodules examined under the microscope prove them to be cancerous. The involvement of the lung was probably secondary.

I certainly made a mistake in the diagnosis, both as to the condition of the gullet as well as that of the lung. It is remarkable the little amount of pain complained of by this patient, when the trouble was so extensive. There is no

history of trauma in the case. I wrote Dr. Woolfolk to give me more information but so far he has failed to do so. This case, I think, illustrates the necessity for more autopsies; without a *post-mortem* it could have been reported, as we see so often now, as dying from "*heart failure.*" Without an autopsy it would have always been a question in my mind as to exactly what she died from; possibly my conclusion would have been that she had a violent coughing spell and the thick, tough sputum had strangled her; however, the *post-mortem* proves that this was not the case.

We know the statements made by some authorities that if there is great emaciation and difficulty in swallowing in patients over fifty years, we should suspect carcinoma or stricture of some kind, but it is equally possible, it seems to me, to have in a neurotic person especially, a spasmodic stricture at any time of life.

Dr. A. M. Vance read a paper (see page 532) on

THE PRESENT STATUS OF CORROSIVE SUBLIMATE IN SURGERY.

DISCUSSION.

Dr. E. R. Palmer: My surgical work is confined almost entirely to minor surgery and yet it enables me to have quite large experience in antisepsis. Take for instance cases like this: A young man working in a tin manufacturing establishment, running machinery that is covered with oil, etc., gets his hand caught and a couple of his fingers are quickly nipped off by the machine; with a dirty, greasy cloth wrapped around it, he is rushed to the nearest doctor's office to have the wound dressed. Now here is a hand that could not be cleansed with sapolio—covered with oil, grit, etc., and it would seem an ideal basis for germ proliferation. The hand was cleansed as well as possible by washing for some minutes with $\frac{1}{2000}$ bichloride solution; the wounds were properly dressed, and there was absolute union of the parts without suppuration. Of course I recognize the value of hot water in cases where it is possible to make the parts absolutely clean and to maintain a condition of cleanliness, but how are we to meet such cases as cannot be cleansed by simply applying hot water; cases demanding a material that acts on oil, etc.; how are we to destroy the germ life that is in such material, in the treatment of such wounds?

I recognize in doing minor surgery that hot water and a solution of boric acid are very useful, and have considerable disinfecting powers, and I use them where it is practicable to make the part absolutely clean before operation. In cases where it is not possible to do this, like the one referred to above, where we have to rely upon something that has positive destructive powers for germs that we can not clean off, I know of nothing better than a sublimate solution.

Dr. D. T. Smith: I am as pleased as surprised to hear from Dr. Vance the views he advances to-night in his essay. Only about a year ago, I was sharply taken to task by him for disapproving of corrosive sublimate as a dressing for wounds. It never was my favorite; I gave it a trial when it first came into vogue, but in the minor surgery which mostly fell to my lot, I conceived that I found it distinctly inferior to the preparation I had been previously using, and so returned to my previous practice. The dressing I have been using from the beginning of my professional career consists of tannin, tincture of opium and claret wine, diluted according to the nature of the case with water. It is practically Burnstead's modification of the French aromatic wine. It is a perfect dressing if the wound be kept constantly moist with it. I have urgently insisted for years, that a substance like corrosive sublimate that forms with the albuminoids a most refractory combination, could not be the proper thing to put between two wounded surfaces with the view of promoting healing. The dressing of laudanum and tannin does not corrode the tissue further than to render them an unsuitable field for bacterial growth, and it does not prevent the surfaces from growing together more perhaps than will the serum itself.

If a tough membrane is formed between wounded surfaces that are expected to unite, it only adds to the task of the leucocytes by whom this substance must be removed; it is these leucocytes after all that afford the protection, much of which has been credited to corrosive sublimate.

And just here, if I may be pardoned the mention, I will venture to claim that I

was one of the first in the field to call attention to this important fact from which Metchnikoff has gained so much honor.

In October, 1884, I read before the Orleans Parish Medical Society an essay entitled "The Role of the Leucocyte," which embraced every leading feature of the doctrine of Metchnikoff relative to the white blood cell. I presented it to the *New Orleans Med. Jour.* and the editor, Dr. Matas, accepted it for a leading article in the next issue. In the meantime a lot of young men got charge of the journal, about eight I believe, and they voted that my article was quite too romantic and fanciful for a scientific publication and returned it to me. I subsequently had it published in a small trade journal, *The Southern Pharmacist.*

Metchnikoff had published earlier than this by one year.

In 1883, he published in two scientific journals in Vienna, but in 1884, he first published in a medical journal, *Virchow's Archives.* I do not think any publication of the doctrine had been made in this country until after I had read my paper, certainly not to my knowledge, so while I cannot claim to have been the original discoverer of this important fact in medicine, I do claim to have discovered it independently.

Dr. O. W. Roberts: I agree with Dr. Palmer that we do not need bichloride solution in operative wounds, but in the class of cases which he has mentioned—railroad injuries, injuries by machinery, etc., where the injured parts are necessarily in a dirty condition, I always feel safer in the use of bichloride solution, 1 to 5000; but I at the same time take the precaution after using the solution, to thoroughly wash the wound with sterilized water so as to get rid of any of the bichloride that may have been left in the wound.

I believe in these cases very frequently, the mercury that is left in the wound not only produces a local effect but also produces a constitutional—the toxic effect of the drug. I had one or two cases some years ago, where the toxic effects of the drug were very manifest, producing distressing gastric and intestinal symptoms which were very difficult to control; in one case I also had salivation. Since then I have never used bichloride in recent wounds without afterward washing it out thoroughly with hot water. In these cases I very frequently get union of the whole surface of the wound—primary union without suppuration. In addition to washing out the wound with hot water after using bichloride, I use over the wound a piece of rubber tissue for protecting the raw surface from the bichloride used in the dressings—I use bichloride and iodoform gauze.

Dr. W. C. Dugan: I will say that my faith is rather weakening in bichloride; I have seen a number of cases which I am sure were aggravated, and union prevented by its use. I remember a case similar to the one referred to by Dr. Palmer, which I saw the 24th of last December. A boy had his finger caught in a machine of some sort and came to my office with his finger crushed and covered with oil and black grease from the machinery; I simply removed it with scissors, shaped the flap and brought it together, washing with hot water, good soap and brush; it healed under one dressing without any bichloride—without any antiseptic whatever. I recently operated upon a case at the Sts. Mary and Elizabeth Hospital, using bichloride which caused excessive necrosis of the wound without any bacteria—simply chemical necrosis—causing a great deal of disturbance in the union. I can recall a number of cases of the kind. I used to use bichloride solution and felt at times that it did a great deal of good. On the whole I am inclined to think that this solution has had its day.

Dr. W. L. Rodman: This is a subject much to my liking—or better disliking. In truth it is a "theme upon which I will fight until my eyelids will no longer wag." While preparing my thesis on pneumonia fourteen years ago, I read Juergenson's article. I remember that he spoke of Niemeyer as the "Quinine hater." I have been known for many years by those with whom I do most of my surgical work, as a bichloride hater. It has served myself and my patients badly. The greatest objection to it is that it causes in many persons, a dermatitis or mercurial eczema, which is no slight thing, as any one who possesses the idiosyncrasy will testify. After immersing my hands in a solution as weak as 1 to 5000, they begin, in four or five hours, to redden and then swell. The itching is simply intolerable and beyond the power of language to ade-

quately describe. The itching continues for several days, being always worse at night, and when desquamation begins I lose my skin as does a snake.

Now if my own was a solitary experience, I would have little ground to seriously advise the discontinuence of bichloride in surgical work; suffering from it as I have done so many times, my observation has been particularly directed to the effect of the drug upon others skins. I could name scores of surgeons, nurses and patients who have been no less unfortunate than myself. Then again every one admits that any cutting instrument coming in contact with the weakest solution of bichloride, will be ruined thereby. With such objections to its use, it has no legitimate place in surgery unless it can be shown to possess advantages over all other agents. I deny that this can be done. In fresh, surgically clean wounds, it is now admitted by a majority of surgeons, that *all chemical agents* had better be dispensed with. We are running to *asepsis* rather than to *antisepsis*. Chemical germicides are only for use in septic wounds. Who uses bichloride at the present day in the abdomen or other large cavity? Formerly every one did. Gauze was formerly immersed in a bath of 1 to 500. Now we rarely see it stronger than 1 to 2000, and generally 1 to 5000. I speak of these things to show that it has had its day. I have seen an abdomen so raw as to look like a tomato as the result of applying gauze (moist) 1 to 2000. You rarely see moist bichloride gauze now at all, because of its irritating properties. Every attempt has been made to overcome the disagreeable effects of bichloride in surgical work and hitherto without success. I have been fighting it here in Louisville for many years single handed; I have borne the brunt of battle in many of our society discussions, and am glad now to know that in the future I am to have such allies as Dr. Vance and Dr. Dugan—they are good fighters and we say to the opposition, "Let slip the dogs of war."

Dr. Wm. Bailey: I only want to say that I could very appropriately express myself in the language that has immortalized one man: "Where am I at?"

Looking over this whole question there have been some wonderful changes. We doctors have been envying surgeons during the last ten or fifteen years, by virtue of the advancement in the art of rendering inactive the various germs by the various methods, solutions, etc., now it seems that they are about to dispense with one of them. I remember very well when carbolic acid was first introduced as an antiseptic we thought it was a wonderful thing; then after a while corrosive sublimate was introduced, which was claimed to be far superior to anything else as it would destroy the germs. Now it seems that neither of these agents has any power to absolutely destroy the micro-organisms.

In cases such as spoken of by Dr. Palmer, it is a question in my mind whether the oil itself is not antiseptic, and whether recovery would be as prompt without the use of bichloride, so long as this will not kill the germs. For a long time I have felt very well satisfied in going to a case of labor, by having my hands perfectly clean, using an antiseptic solution for bathing, that everything was entirely safe and I could make an examination with a great deal of confidence. Now it appears that the so-called antiseptic solutions are of no benefit—"Where am I at?"—Have you anything that is of benefit?

Dr. C. Skinner: I discarded bichloride solution about a year ago and have been watching the results.

In abdominal work I employed a silk ligature and sutures which had been soaked in a solution of bichloride—making the "ideal suture." The bichloride acting upon the tissues to form the albuminate of mercury which was supposed to be germ proof. This suture I discarded for the silk worm gut and had three consecutive cases of stitch abscesses. The cause I traced to lack of care on the part of nurses in sterilizing instruments and material, and now since I attend to all this work myself I see no pus. It is not safe to intrust this all important work of sterilization to nurses, for they do not as yet realize its importance. I think we can get just as good results from the use of clean boiled water in surgical work, if our instruments and everything else used in the operation are properly sterilized, as by the use of any antiseptic solution yet introduced.

Dr. A. M. Vance: I have not much to say in closing. I am very glad the

subject has been so thoroughly discussed. I do not think cases of the character Dr. Palmer mentions prove anything for bichloride. Of course, the wound should be cleansed of cinders, grease, etc., but I fail to see how corrosive sublimate could possibly be of benefit.

I feel sure that Dr. Roberts will recall a number of cases of amputation that have suppurated without his being able to account for it, except for the fact that he used solution of bichloride of mercury 1:2000, which, undoubtedly, produced necrosis. I think this solution is especially harmful in fresh wounds, as it not only will not absolutely destroy microorganisms, but it prevents healing because of the necrosis it produces.

Regarding Dr. Bailey's remarks, the history of medicine, as well as surgery, is constantly undergoing change. He is probably now using medicines that he did not dream of five years ago, and discarding remedies that he formerly used constantly.

I fully agree with what Dr. Rodman has said, that corrosive sublimate has had its day, and that, in a few years more, it will be regarded in about the same light in surgical practice as carbolic acid is to-day.

The Treatment of Acute Intestinal Obstruction.*

L. Rehn, (*Archiv. für Klin. Chir.* bd. xliii, hft 3. 4,) speaking from personal experience, advises early surgical interference in cases of acute intestinal obstruction, and presents on the whole very good results. He gives a short history of thirteen cases of acute intestinal obstruction with ten recoveries through operative interference, most of which necessitated considerable manipulation.

In some cases the diagnosis regarding location was not clear, while in others he was able to locate it definitely. Most of the cases were the result of strangulation or torsion. One was due to an acute angle produced by mechanical pressure, resulting from suppurating masses; this was at once relieved by simply removing the pus pockets. In another case the occlusion was due to a displacement of the flexura sigmoidea through pressure induced by an abdominal pregnancy.

As usual the conditions found were rarely alike in two cases. The diagnosis was in most cases easy, eight times fecal vomiting was present. Rehn places great value upon auscultation of the abdomen in order to aid in localizing the peristalsis in cases where this can not be seen.

The author wishes to make a distinct classification between those cases in which obstruction arises outside of the intestinal wall, and those in which the lumen of the bowel is obstructed from the interior. This latter can only be considered secondarily in acute strangulation, since the fate of the tried bowel may be already sealed before any marked symptoms of obstruction of its lumen present themselves, hence strangulation of the bowel, in the author's opinion, can be more certainly diagnosed if the attack is sudden, grave; accompanied by severe pain and followed soon by collapse. Such cases must be treated on a similar plane as strangulated hernia, namely, prompt surgical interference.

The author believes that such strangulations are more dangerous to the vitality of the bowel than cases of strangulated hernia. The complication with suppurating processes, such as typhlitis, require that the attention be directed to a careful removal of all products of suppuration. In cases of chronic increasing obstruction the author gives no precise regulations regarding diagnosis or treatment.

If operation becomes necessary he prefers enterostomie, and only in those cases where a definite knowledge of the location and nature of the obstruction is present. An exploratory incision may often be necessary to establish this.

*Translated for the MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

Black Eye.

There is nothing to compare with a tincture or a strong infusion of capsicum annum, mixed with an equal bulk of mucilage or gum arabic, and with the addition of a few drops of glycerine. This should be painted all over the bruised surface with a camel's-hair pencil, and allowed to dry on, a second or third coating being applied as soon as the first is dry. If done as soon as the injury is inflicted, the treatment will invariably prevent the blackening of the bruised tissue. The same remedy has no equal in rheumatic, sore or stiff neck.—*Medical Times.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 = 18 = 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 8TH, 1893.

EDITORIAL.

PROFESSIONAL COURTESY.

Anent professional ethics, whether the code shall or shall not be revised, THE REPORTER calls attention to a fundamental element that appears to have escaped notice. The factor is of such importance that if its faults remain uncorrected every attempt to revise or reform a code of rules will prove futile; while if the faults are eliminated there will be no necessity for the existence of a code. This important factor is the *personal equation*, and the more important defects are summed up in the term *selfishness*. Correction of the defects of this fundamental factor unravels the entire tangle of the "Code of Ethics."

The solution is so simple and practicable that in all probability it will receive but scant consideration. Its simplicity may prove an objection in some quarters for it would bear equally and alike upon every individual in the profession, and might subject some enthusiasts to the disagreeable suspicion that their loud talking was prompted by some motive other than anxiety for the public weal. Its practicability might not inspire support from all quarters, but the profession at large would regard it with satisfaction, in that each individual would be charged with the oversight of but one man, would be relieved of the necessity of searching out and contemplating the shortcomings of his fellows and would be enabled to devote the considerable time thus economized to scouring possible rust specks from his own escutcheon.

The key to the whole problem—and there is but one key—is the good old-fashioned Golden Rule.

This rule is as applicable to professional intercourse in medicine as it is to any other relation in life.

It would be easily applied and readily observed were medicine practiced in a more disinterested spirit. Were the contribution to scientific knowledge the ulterior motive and the relief of suffering the immediate object of each practitioner, there would be no room for envy, no mo-

tive for jealousy, no opportunity for backbiting and no excuse for disparagement. Science requires the keenest scrutiny, the most severe tests and the fullest and freest discussion of every offered effort at advancement, but it also requires the total elimination of the personal equation. Unfortunately few discussions of medical innovations are entirely scientific in this latter respect.

A disciple once told the Master that an unauthorized person, over in a neighboring locality, was casting out devils in his name, and that he had been forbidden to continue the practice. The Great Physician responded—"Forbid him not, for he that is not against us is for us." He recognized only the fact that one engaged in the god-like office of ministering to the afflicted was neither more or less than a brother.

But in modern times devils must be cast out in the good old orthodox way (orthodoxy is *our* doxy, all else is heterodoxy), or we may not recognize the man who does it. Having learned that the stones we have been casting at our heterodox brethren have served only to build higher the pedestal on which they pose before the world, we begin to look around, and if we notice any one of our own sacred caste doing things in a brilliant or original manner, "we rise up and smite him with misrepresentation and calumny." Yea, verily we call him a prevaricator. We prove not only that he does not do what he claims, but we bring witnesses who testify that he does it in a very unorthodox way. That his procedeures are not justifiable, we have documentary evidence in the shape of an unbroken line of authorities beginning before the birth of authentic history and continuing even to this day. If this gentle expostulation does not lead our brother from the errors of his way, we formulate an ultimatum that certain conditions are incurable; that, for reasons we proceed to name, certain methods are "brutal and inhuman and not excusable on any reasonable ground." This ultimatum we tie on the tail of our sacred bull, Infallibility, and turn it loose to edify the public.

When cowardly insinuations that "a prominent professional man" is using just such methods, and for the very reasons that we have announced to be false and dangerous, reach our surprised ears, we shake the head and whisper—"Is it possible!" Well I am not surprised after all. He is afflicted with a swelled head. In fact I have long regarded him as a very dangerous man. Tomtit says he stole some cases from Blaggard. He says he is willing to swear to it, for Mendax told him that Jacquass heard it discussed at Allgab's table. Now don't you think some measures should be taken to end this disgraceful state of affairs? If we let this thing go unchecked there is no telling who will be exposed next. Confound the fellow! He knows too much, and we must muzzle him. Well, so long! If there is anything I despise it is a mischief-maker. Scavenge is on his rounds now and when he sees you doubtless he will give information of personal interest to you."

If our erstwhile companion remains unconvinced we hail him before the Council. This conclave of grave and reverend seigneurs we persuade to sit on him, and, in order to make their influence ponderable, we call to their assistance some modern Samson with a reputation of slaying thousands with the jaw-bone of an ass—even his own.

If all these things move not the offender we resort again to painstaking and industrious lying.

This hypothetical process is duplicated in every community that contains a live, progressive and successful man. What is true of reformers in all other lines obtains in the medical profession likewise, and is due largely to the variable

personal equation. This unfortunate condition is not true, perhaps, of the majority of individual members, but it does mark the profession collectively. This may seem paradoxical, but it is true, nevertheless, as history abundantly shows. For instances, concealing the skeletons in our own closets, we mention but one or two remote cases.

When McDowell published an account of his first abdominal section, the editor of a leading English journal denounced him as a liar—then apologized for the insult.

No member of the English profession of to-day likes to hear the name of Baker-Brown. The story of the jealousy and meanness that drove Baker-Brown out of the London Obstetrical Society, ruined him financially and eventually landed him in a mad house, is too recent to moderate the shame of the profession.

But similar efforts to bury under a load of contumely the men whose genius builds the monuments of medical progress in the closing decade of the Nineteenth century, are being made to-day, both at home and abroad.

In its ultimate analysis the inspiration is the defect of the personal equation—selfishness. It is that which compels the existence of a code; and so long as it remains sovereign in influence no code can modify it. When eliminated no code will be necessary.

THE MEDICAL EXAMINER'S BILL FOR PENNSYLVANIA.

The bill establishing a State Board of Medical Examiners has passed the House. The present bill may not be perfect, but it is a safe one upon which to base future legislation.

The bill provides for the appointment by the Governor of three boards for the examination of all applicants for license to practice medicine or surgery. Each board to consist of seven members whose term of office shall be three years. One will represent the Medical Society of Pennsylvania, one the Homœopathic Medical Society of Pennsylvania, and the third the Eclectic Medical Society of Pennsylvania. The appointments are to be made from the full lists of members of these societies.

The duty of these boards ends with the examination of applicants and the recommendation to the Medical Council of Pennsylvania, which is established by the same bill.

The Council will consist of the Lieutenant-Governor, the Attorney General, the Secretary of Internal Affairs, the Superintendent of Public Instruction, the President of the State Board of Health and the Presidents of the three State Boards of Medical Examiners. It will be the duty of the Council to supervise the examinations conducted by the examining boards, and to issue licenses to those who have successfully passed the requisite examination or have been recommended for license by one of the Boards.

C. Chlorodyne.

This is the name given at the Walajabad Mission Dispensary for a chlorodyne much used there in cholera cases (*Calcutta Medical Reporter.*) The formula is:

℞

Spt. menthæ. pip.	ʒij.
" camph.	ʒij.
" chloroform.	ʒij.
Tinct. capsici	ʒij.
" zingib.	ʒij.
" catechu	ʒvj.
" digitalis	ʒj.
Acid hydrocyanic. dil	ʒij.
Glycerini	ʒiij.
Spt. vini. rect.	ij. M.

mxx. in ʒj. of water every fifteen minutes, until vomiting and purging stop.

When the cases come, Dr. W. Walker states that treatment is begun at once with 20 drops of the chlorodyne, in a teaspoonful of water, and if necessary the same amount is given every fifteen minutes; but it is seldom found that more than one or two doses are required. At the same time the usual specific treatment is carried out.

TRANSLATIONS.

RUPTURE OF THE BILIARY PASSAGES IN CONTUSIONS OF THE ABDOMEN.†

In *Le Bull. Med.*, Feb. 5, 1893, Routier, of Paris, comments upon the progress made of late years in the surgery of the abdomen; that through this advance we are now able to treat successfully lesions that otherwise would only be discovered on the autopsy table, such as rupture of the intestines. He reports a case of traumatic lesion of the liver occurring in a little boy of thirteen years, who was seen in his hospital service at Cochin, suffering with all the signs of an acute peritonitis—distension of the abdomen, extreme pain, shriveled features, pulse small and thready, tongue dry, repeated vomiting, rather bilious. These symptoms had suddenly developed after a kick in the right hypochondrium which had provoked an immediate syncope. The bowels had been unmoved since the traumatism, the urine was scanty and red; fortunately the child passed some flatus. This fact itself assured the integrity of the intestines and rendered the course to be pursued very simple. Two large bladders full of ice were applied to the stomach; the diet was absolute, and a small injection of morphine was made. The amelioration was rapid, and so decidedly so that on the sixth day, in spite of advice to the contrary, the child was removed to its home. This was a bad move for, two weeks later, his mother brought him back in a pitiable condition. Now the child was weak and emaciated, with alternating diarrhœa and constipation; his peritonitis was rather sub-acute although with fever, but the local signs especially had much changed. When on his first sojourn in the hospital his abdomen would scarcely tolerate touching, so great was his pain, but now palpation, although still painful, was nevertheless possible. It was also easy to recognize fluctuations throughout the whole extent of the right side of the abdomen. The tympany appeared general at the first examination, but now while the whole left side remained tympanitic, the entire right side of the belly was flat. The mother said that when in his seventh year he had been attacked with symptoms analogous to those that had followed the kick, resulting from a fall upon the stomach, but not so grave, consisting mainly in alternating periods of diarrhœa and constipation. This history threw Routier off the track and caused him to modify his diagnosis. He thought now that the recent traumatism had lighted up a dormant tubercular peritonitis, and with the idea of treating a peritonitis of this nature he proposed to the mother the performance of laparotomy. An incision was made in the median line below the umbilicus, and he immediately came down upon an oval mass of agglutinated intestines, adherent to the anterior walls, so that considerable care was required to prevent tearing them. As soon as he had opened the peritoneum there escaped about a liter and a half of a greenish-brown liquid resembling bile in every particular. He again modified his diagnosis to that of rupture of the biliary passages, especially as the false membranes did not have any of the tuberculous appearances and as there were no traces of granulations upon the intestines. These membranes were very thick in the middle line and especially towards the liver, the inferior surface of which they completely masked. There was thus formed a sort of antero-posterior wall by the mesentery, the agglutinated coils of intestines and the omentum which acted as a barrier to the liquid. However, as this wall approached the pelvis it became less complete, the false membranes disappearing and the intestinal coils preserving their normal lustre, although tinged green by the bile. It was thus that the fluid was able to penetrate into the pelvis and to rise again, although in small quantity, on the left side of the mesentery. The thickened masses of exudate which concealed the lower surface of the liver, and which were believed to have a curative action, were not removed; the fluid was allowed to escape and the abdomen was closed. The after course was very simple.

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

Eight days after the operation there was no reproduction of the effusion, and some days later the child went out cured. There was no doubt as to the nature of the lesion; the traumatism had caused a rupture of the biliary passages and the effusion of the bile had produced the partial peritonitis which the operation had caused.

These cases are quite rare, but curious to note they are all the same, so that the observations that Routier has been able to collect appear all based the one upon the other. From these observations and from the results of experimental pathology he has been able to trace a sort of schema of this variety of abdominal traumatism. In nearly every case there is a history of abdominal contusion from a force whose application was made upon a small surface —in the above case, the end of a boot— the tip of a carriage pole, as in the case of Arbuthnot Lane; the end of the beam of a fire engine, as in Drysdale's case, or the end of a wagon shaft, as in the case cited by Uhde. However, the cause is very often obscure. In the observations of Fryer, of Thompson, and of Landeser there is simply made mention of a violent shock. To explain the rupture of the bladder or bile passages, Routier willingly accepts the following hypothesis: The contusing body acting by a sharp extremity and striking the patient from below upwards in the subhepatic region takes the abdominal wall by surprise, immediately effacing the lumen of the ductus choledochus or of the gall-bladder, by pressing against the lower surface of the liver retained in the concavity of the diaphragm; the bile imprisoned in the bladder or canals is not able to escape; the pressure increases and the liquid causes the walls to give way.

He gives as the result of his researches and practical experiences the following conclusion: When a surgeon is brought face to face with an abdominal contusion, especially in the hepatic region, and there is reason to believe that there does not exist an intestinal rupture, it is better to bear in mind the possibility of rupture of the bile passages. The patient then should be placed in a state of absolute repose with restricted diet, ice should be applied over the abdomen, opium administered internally, and palpation observed to gauge the moment when the general symptoms become quiet. Then all that must be treated is the abdominal effusion, and experience has proven that nothing is comparable to a simple laparotomy. The result is always satisfactory.

A Case of Incipient Ischiatic Hernia.*

The patient, a woman, aged 41, had been suffering for nine days with constipation and fecal vomiting; was admitted into the surgical department of v. Hacker.

A fracture of the left thigh was at first regarded as the cause of the symptoms of strangulation present. Herniotomy, however, revealed no such strangulation. Laparotomy was resorted to on the same day by v. Hacker, who found that near the end of the ileum, about two finger breadths (spannen) of the bowel had passed through a recess of the parietal peritoneum and become strangulated. This recess was found in the left portion of the small pelvis in the region of the incisura ischiatica.

After releasing the strangulated portion of the bowel, and closing the abdomen, the symptoms of incarceration were at once relieved. The patient, however, died on the sixth day of lobular pneumonia of the right lung.

The author was unable to find any cases in literature quite analogous to his, since the anatomical descriptions of such hernia usually place the sac in another position to the obturator and hypogastric arteries than in his case.

Langer's explanation, however, is that all hernia of this nature, which passed through the opening between the incisura ischiatica major and the upper margins of the pyriform muscle, originates, more or less, from internal hernia, and for that reason regards his case as one in its early stages. Until the present time eleven cases have been published under this head, the author's being the first in which the condition was relieved by operative means.—(A. Langer, *Centralb. für Chir.*, No. 9–'93.)

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

For April contains

A Contribution to Cerebral Surgery,

By Drs. Charles McBurney and M. Allen Starr. The questions of the diagnosis, localization and operation for the removal of tumors of the brain are discussed and three cases of brain tumor reported in which operation was performed.

CASE I. Sarcoma of the left frontal lobe. Successful removal, subsequent death. The case is reported in full with cuts showing the site and appearance of the tumor.

CASE II. Fibro-sarcoma of the cerebellum and pons varolii; staggering away from the side of the tumor; operation; death. The autopsy showed that it would have been impossible to have removed the tumor owing to its situation.

CASE III. Glioma of the cerebellum; characteristic staggering; operation; death. The tumor was not removed, as it occupied the vermiform lobe of the cerebellum and was not discovered during life.

Operations on the brain more frequently than in any other part of the body, are exploratory, and, in spite of the constantly increasing knowledge of the subject, the operator will probably always be in doubt as to the possibility of removal of the tumor until it is reached. While exploratory operations in other parts of the body are often simple and devoid of risk, it is not so in the brain, where unexpected difficulties, even serious accidents are liable to occur at any stage of the operation. The chief danger is from hemorrhage, which begins from the moment the scalp is cut and varies greatly with different cases. The incisions in the scalp should be free and horse shoe-shaped, the author's preferring the method suggested by Wagner, which consists in cutting through the skull with a chisel in the line of the scalp incision, the scalp flap not having been turned back. This bone flap with scalp flap still attached is then pried up and turned back, thus exposing as large an area of dura mater as the original incision outlined. To open the dura the authors prefer to cut directly down upon it with the knife at a point an eighth or a quarter of an inch away from the bony margin. When an opening is made, small blunt scissors may be introduced and the whole flap of dura, similar in shape to the bone flap, turned back. Picking up the dura mater with a tenaculum is more likely to be accompanied by a wound of a vessel in the pia mater. As a rule if removal of a tumor is begun it must be completed. Hemorrhage from a wounded vessel in the pia mater is best controlled by the cautery if the vessel is small; larger ones may be compressed by a sponge in the hands of an assistant and the cautery or ligature applied later if necessary. A wound in a sinus had best be packed with gauze, if large. If small enough it may be closed by one or two pairs of pressure forceps which may be left in position for two or three days. It is is useless to try to ligature or suture a wounded sinus. Free hemorrhage from the cavity left after removal of the tumor should be met with gauze packing. In operating on tumors of the cerebellum the danger of wounding the sinuses is too great to allow of the application of the method of entering the skull mentioned above. Here it is better to sacrifice the bone and remove a button with the trephine, enlarging the opening if necessary.

The diagnosis of cerebellar disease is asye; headache, vomiting, vertigo, blindness and staggering being the symptoms almost uniformly found. It is yet almost impossible to locate accurately the disease within the cerebellum. The symptoms of greatest importance in the location of cerebellar disease appear to be those arising from the involvement of the cranial nerves upon the base. The disease commonly lies upon the side upon which those nerves are affected.

The two cases reported bring the number of operations for cerebellar disease up to thirteen. In six cases the tumor was not found at the operation and the patient died. In one case the tumor was not found but the patient was alive at the time of the report. In two cases the tumor was removed, but the patient died. In two cases it was found but could not be removed and the patient died. In one case it was found, not removed, but the patient lived. In but one case was the tumor successfully removed. The percentage of deaths after cerebellar operations thus far has been 77 per cent., while that after cerebral operations has been 51 per cent. If the results of the cerebral operations be combined with those of the cerebellar, we find that the total number of patients operated on for intra-cranial tumors has been eighty-seven, and that of these, 40, or 46 per cent., have proved successful, the patients recovering.

This issue contains two papers on

Symphysiotomy.

Dr. Henry J. Garrigues continues the report of a successful case begun in the March number. His conclusions are as follows: The distance between the ends of the bones after symphysiotomy can readily be increased to two and three-fourths inches without injury to the sacro-iliac joints. If the separation is carried to three and one-eighth to four inches the joints, one or both, crack and open. The indications and limits of the operations are discussed and for flat pelves, found to lie between two and three-fourths and three and one-half inches. In the generally contracted pelvis the author places the upper limit at four inches, C. V. In performing the operation the operator sits on a chair between the legs of the patient, which may hang down over the end of the table or

lie outstretched during the first incision, but during the incision of the symphysis should be held bent in hip and knee-joint, moderately separated with the feet high. The transverse incision into the recti muscles advocated by Morisani, the author thinks is not necessary and weakens the abdominal wall. After cutting down on the symphysis, the finger is introduced behind the bone and Galbiati's falcetta introduced, the cut being made from behind forwards and from below upwards. In this way the bladder is avoided. The whole symphysis, inclusive of the subpubic ligament, should be cut. The urethra is protected against injury by being held over to the right side by means of a long metal catheter. The bladder and vagina are guarded by the finger held behind the symphysis or by passing a director. Assistants should press moderately on the trochanters, and in this way avoid too great strain on the articulations. The soft parts should be held apart during extraction. As to the furthering of labor after the symphysis has been severed, the author thinks the woman should be delivered at once and not left to nature as Morisani advises. The common rules of delivery hold good—forceps for the engaged head, turning for a head movable above the brim. If the placenta does not come away within fifteen minutes after delivery of the child it is better to loosen it artificially before closing the wound. After delivery of the placenta the bones are brought together by pressing on the trochanters,and deep sutures introduced through the skin, adipose and fibrous tissue down to the bone. Great care should be taken to see that the bladder and vagina do not get in between the ends of the bones. Broad bands of rubber adhesive plaster surround the pelvis and the patient should lie with outstretched legs as this position tends to bring the end of the bones together. The author thinks it safe to let the patient get up at the end of three weeks. In relation to other operations, the operation of craniotomy on the living child, which has been so universally condemned, will vanish from the list. Induction of premature labor will be much restricted. The improved Cæsarean section holds its own when the conjugate is below 2¾ inches. The operation of symphysiotomy should be performed as soon as labor is sufficiently advanced, as delay only adds to the dangers. The operation should only be undertaken by the skilled operator.

[The whole paper is a clear dispassionate statement of the entire subject of symphysiotomy and is a valuable contribution to our knowledge of the operation.—Ed.]

The other paper on symphysiotomy is by Dr. William T. Lusk and is the report of a case in which the operation was performed on a primi para who had been in labor for twenty-two hours. There was a brow presentation and version and extraction by the forceps had been tried by the attending physician without result. The child lived seventeen hours; the mother died on the afternoon of the day following the operation. The reporter does not think the operation responsible for the fatal result.

Dr. George M. Edebohls concludes his paper on "Movable Kidney." The author describes the operation of nephrorrhaphy as he is accustomed to perform it, and states that the mortality is practically *nil*. For buried sutures to fasten the kidney to muscle and aponeurosis, he uses silkworm gut exclusively. The paper included the detailed report of the twelve cases in which he has performed the operation.

Dr. D. D. Stewart contributes a paper on "The Prevention and Treatment of Cholera by the Naphthols." The paper includes the bacteriological report by Dr. George M. Sternberg on the subject.

Dr. L. Duncan Bulkley discusses the "Internal Treatment of Lupus Erythematosus with Phosphorus" giving the formula of the solution used by him. The paper included the report of cases cured or much benefited by the treatment.

Dr. Leo Newmark presents "A Contribution to the Study of the Family Form of Spastic Paraplegia," reporting the cases in two families in which the disease occurred. The paper is illustrated with the photographs of three of the patients.

THE VIRGINIA MEDICAL MONTHLY

for March contains an article by Dr. William A. Thom, Jr., on "The Quarantine of the Future," in which the glaring defects of quarantine as now constituted are reviewed and suggestions made for the betterment of the service. He suggests the appointment of a commission of five, by the Federal government, who shall have supervision of quarantine matters and be assisted by a corps of inspectors. The plan also includes the establishment of disinfecting plants at various points and regular reports from consuls as to the sanitary condition of the country in which they are stationed.

Dr. R. L. Payne presents "Some Practical Observations on Treatment of Typhoid Fever." In speaking of hemorrhage from the bowel and the generally accepted idea that it is a most unfavorable symptom, he says he has "seen many a case in which the effect of the hemorrhage seemed to be beneficial when it was arrested before dangerous collapse came on." Quinine he thinks a bad antipyretic and as a tonic it has not answered as well in his hands as serpentaria. Quinine he thinks increases the nervous symptoms even if it does not cause them. Antipyrin, antifebrin and others of the coal tar products have answered well in some instances, but in general are uncertain and the prostration which sometimes follows their use more than counterbalances the benefit. As an antipyretic there is nothing, in his opinion, like cold water, either in the form of the cold pack or frequent sponging over the whole body.

Dr. Simon Baruch contributes a paper on "Practical Data of the application of Water in some Intractable Diseases," reporting a number of cases cured by a water treatment. He sums up his paper as follows: "We pos-

sess in this method a valuable auxiliary to methodical treatment of many, though not all, acute and chronic maladies. In many chronic diseases it has proved so successful after failure of medicinal remedies, that no case should be yielded up as hopeless until hydrotherapy, in some form, has been tried. Domestic treatment will suffice in most cases, but if these fail, a methodical treatment under an expert hydrotherapeutist may be of advantage to the patient."

Dr. O. M. Smith reports a case of "Tracheotomy at Nineteen Months—recovery." The child had been given half of a chinquapin by her brother which lodged in the trachea. It was impossible to dislodge the fragment and tracheotomy was proposed but rejected by the parents for three days till the child developed a traumatic pneumonia. At the operation the fragment was driven out through the incision and five days later the husk was also discharged. The child made a perfect recovery.

Dr. John Walker reports a "Case of Gunshot Wound through the Knee-joint, with recovery without limp." The ball entered the knee at the tibia-femoral articulation on the inner side of the joint, passing through the joint and lodged under the skin on the outer side of the limb. The ball was removed, the wound washed out with 1 to 2000 bichloride of mercury solution, dusted with aristol and put on a long splint, extending from the hip to the ankle, thus securing absolute rest. At the end of the sixth week the patient had perfect use of the knee with normal motion.

Dr. A. S. Priddy reports a case of "Abdominal dropsy mistaken and operated on for an Ovarian Cyst."

Dr. Frank T. Chamberlin reports an abscess of the epiglottis in which recurrence took place after the evacuation of the abscess cavity. The report is illustrated with cuts of the appearance of the abscess.

Dr. T. N. McLaughlin presents some "Notes on the Therapeutical Action of Thiol in the Treatment of Skin Diseases." He uses the drug extensively in the various forms of eczema and reports good results from it. In furuncles and in one case of carbuncle it proved highly beneficial. It can be administered internally in doses of from three centigrammes to one gram, three times a day. Deleterious effects have not been observed. It possesses the following advantages over ichthyol: it is odorless and does not stain the clothing. It can readily be removed from the surface. All the desirable therapeutic properties possessed by ichthyol may be claimed for thiol.

The other papers in this month's magazine are: "Hysterectomy with report of a difficult case successfully treated," by Chas. G. Cannaday.

"Certain animal extracts" by Dr. William A. Hammond, which has already been noticed in THE MEDICAL AND SURGICAL REPORTER for February 11th, page 235. "Case of Early Diagnosis of Tubal Pregnancy" by Dr. Hugh M. Taylor which has been reviewed in the THE MEDICAL AND SURGICAL REPORTER for April 1st, page 513.

JOURNAL OF CUTANEOUS AND GENITO-URINARY DISEASES.

The March number contains an article by Dr. Hyde on "The Cutaneous Cicatrices of Syphilis" of which fuller mention is made elsewhere in this issue.

Dr. Morison reports "An Unusual Case of Syphilis" which is merely a record of a case of simple syphilis over-treated in the beginning, which was rendered obscure by a peculiar susceptibility of the system to both potash and mercury.

Reports of "A Case of Acute Circumscribed Œdema of the Skin" by Dr. Russell, and "A Case of Congenital Syphilis" by Dr. Hessler complete the list of original communications.

Under "Society Transactions" are reported the proceedings of the New York Dermatological Society, and Section of Genito-Urinary Surgery of the New York Academy of Medicine.

THE NEW ZEALAND MEDICAL JOURNAL.

The quarterly issue for January offers fourteen papers.

Dr. Cleghorn reports the "Treatment used in five cases of Chronic Suppuration, without drainage by the Barker Method," which consists in making small incisions, the thorough removal of the pyogenic membrane by scraping with the finger or special instruments, washing out with large quantities of very hot water, filling the cavity with iodoform emulsion which is squeezed out and bringing the edges of the incisions together with silk sutures without any provision being made for drainage. Dr. Cleghorn also reports "Two Cases of Cerebral Tumor, Localizing Symptoms, Operation." The object in reporting these cases is to obtain an expression of opinion as to the advisability of further operative procedure in case symptoms return, as it seems only too likely they will do. The doctor contributes in addition to these two papers, one as a report of "Two Cases of Acute Purulent Synovitis (knee and ankle) treated by incisions and washing out well with Peroxide of Hydrogen. No drainage. Recovery, with perfect joints."

"Radical Cure in Strangulated Hernia," and "Hydronephrosis of Kidney" by Dr. Gillon, together with a "Report of the Examination of Fallopian Tubes in Three Cases of Tubal Gestation" by Dr. Mackenzie, complete the more important papers.

THE THERAPEUTIC GAZETTE

for March contains five original papers; two are clinical lectures, and three leading articles or editorials. We select from these as the most important

Sympathetic Irritation and Sympathetic Serious Iritis with Cases.

Dr. de Schweinitz in speaking of the affections in which one eye is implicated as the result of disease or injury to the other—sympathetic irritation and sympathetic ophthalmitis—repeats some rules which cover the ground as well as it is possible to do. The

rules are quoted from those which are given by Mr. Swanzy.

"You should perform enucleation, or one of its substitutes, on,—

(1) An eye with a wound which involves the ciliary region to such an extent that sight is immediately destroyed, or that its ultimate destruction by the process of inflammation is practically certain.

(2) An eye which has been wounded in the dangerous region, and in which severe inflammation of the iris or ciliary body has already begun, even if sight is not destroyed.

(3) An eye which contains a foreign body which judicious efforts have failed to extract, and when much iritis is present, even if sight is not destroyed.

These three rules, you will observe, apply to preventive enucleation,—that is to say, the operation is performed in order to check sympathetic disease.

Now let me quote you two which should be your guide, provided the sympathetic disease has already begun.

1. You should perform enucleation, or one of its substitutes, on an eye whose sight has been destroyed, even though sympathetic inflammation has begun in the sympathizing eye, because by this means you remove a source of irritation and hope to render the treatment of the sound eye more effectual.

2. You should *not* perform enucleation, or one of its substitutes, on an eye which has been injured, but which retains some vision, when sympathetic inflammation has begun in the sympathizing eye, because in the end it may prove to be the more useful organ.

Under the last-named circumstances you must employ the medicinal treatment suited to the excitor, as well as that needed by the sympathizer. Generally this treatment consists in the frequent instillation of atropine, local blood-letting, and, if the patient is sufficiently robust, the use of mercury in some form, preferably protiodide by the mouth or inunctions, to the point of tolerance, but not to that of salivation, tonic doses of quinine, and concentrated, nourishing food. The light should be excluded, if necessary with a bandage, but there is no objection to the patient having proper exercise, which usually may be given in the room to which he is almost of necessity confined. Should this not be practicable, he may be taken out with eyes properly protected with bandages."

The Treatment of Gonorrhœa.

Dr. Christian's paper is the result of careful observations made at the genito-urinary clinic of the University Hospital. He offers the following summary of two methods of treatment carried out.

Number of cases of acute gonorrhœa treated by injections at a comparatively early period of the disease, 150; uncomplicated with posterior urethritis or epididymitis, 85; developing posterior urethritis, 52; developing epididymitis, 13.

Acute gonorrhœa treated without injections till the subsidiary stage was well developed, 150; uncomplicated with posterior urethritis or epididymitis, 134; developing posterior urethritis, 12; developing epididymitis, 4.

After a comparison of the results obtained by these two methods of treatment, it would seem that there is but one conclusion to be drawn,—namely, that the use of injections, prior to the subsiding stage of acute gonorrhœa, acts, in quite a large proportion of the cases, as an exciting cause in the production of posterior urethritis and epididymitis; and on this account is not to be considered as the best treatment of the disease.

All patients at the venereal dispensary of the University Hospital are now put upon the internal use of a capsule containing five (5) drops of oil of sandalwood and five drops of oil of copaiba, with one drop of oil of cinnamon. From four to eight of these are taken daily for the first three weeks.

When the "morning drop" persists, an injection of sulphocarbolate of zinc and hydrastis is used.

It is not claimed for this plan of treatment that it in any way cuts short the duration of the disease, but only that it aids in preventing the frequent occurrence of posterior urethritis and epididymitis, the two most troublesome complications of gonorrhœa."

THE OPHTHALMIC REVIEW.

To the February number Dr. Ernest F. Maddox of Edinburgh contributes a paper on

The Prescribing of Prisms.

He passes in review the various methods of testing the latent conditions of equilibrium for near and distant vision by the "finger," "rod," and "card" tests, and the test of the "relative range of convergence," by which is meant the extent to which convergence can be artificially increased or relaxed (by adducting prisms) while accommodation remains the same for an object at some definite distance. For the "rod" test Dr. Maddox states that a series of small glass rods about an inch long should be used, "arranged parallel to each other, and in close contact. Any one can make this for himself by breaking up a long glass rod of about one-eighth of an inch in diameter into short pieces of equal length, laying them side by side on a hard surface, to get them perfectly level, and then fixing their ends with sealing wax. The advantage of this form is the ease with which it is held opposite the patient's pupil, for one of the rods must be in front of it. Dr. Maddox refers to the remarkable persistency of hyperphoria. He writes: "In a doctor of my acquaintance I noted at two separate times, so far apart as two years, a persistent hyperphoria of exactly $1\frac{1}{2}°$. The headache from which he has suffered for many years is very likely connected with it, but I have not yet prevailed on him to try prisms."

An abstract of a paper by Dr. E. Emmert (Bern) on "Keratits Dendritica and Herpes Cornea Febrilis" is to a great extent of a controversial character.

PERISCOPE.

MEDICINE

The Nasal Douche.

Dr. L. A. Dessar, in *Inter. Jour. Surg.*, says: The following rules should be observed in the use of all nasal douches:

1. The handkerchief should not be used for at least ten minutes after douching, inasmuch as in blowing the nose, any fluid remaining in the nasal passages may by a Valsalva action be forced into the Eustachian tube.

2. After douching it is advisable for the patient to remain indoors, so as to avoid exposure to the cold air.

3. During the proceeding the patient should not be disturbed or excited, as this may give rise to an involuntary attack of sneezing, coughing, or swallowing, and thus render it possible for fluids to enter the middle ear.

4. Before beginning the douching a careful examination should be made to see whether both nostrils are free. If one of them is found to be obstructed the douche should be used on the affected side.

5. Plain water should never be employed for douching, as it loosens the nasal epithelium. The addition of a small amount of sodium chloride prevents this action.

6. Concentrated solutions should never be used as a douche.

7. It is not advisable to douche the nose more than three times daily. As a rule, its application morning and evening is sufficient.

8. The quantity of fluid introduced should not exceed ten ounces, the average amount varying from five to ten ounces; *i. e.*, from one to two douche cupfuls for each nostril.

9. The fluid should always be luke-warm.—*Med. Brief.*

Symes (W. L.) On Hiccough.

The writer regarding this as a reflex act believes that the sympathetic connections of the Semilunar ganglion convey the centrifugal impressions rather than the phrenic nerve. His reasons are as follows:

The diaphragm appears to contract *before* the laryngeal muscles, pointing to a closer and more direct communication with the gastric portion of the vagus than even the recurrent laryngeal.

2. The course of the phrenic nerve is healthy, and its respiratory function perfect.

3. The patient has no control over the spasm, while the phrenic is always subservient to one's will.

4. Remedies applied to the origin or course of the phrenic, ice-bags, compres spine, such as blisters, or to the cervical sion, etc., etc., have no effect; while those directed to the diaphragm, stomach, and solar plexus, are generally curative.

5. The connections between the pneumogastric and phrenic by means of the 3d, 4th, or 5th cervical nerves, are remote, and if this were the route taken, the impression must travel more than double as fast on the phrenic than it does on the recurrent nerve, since it reaches the diaphragm before the larynx—conditions which are unphysiological.

6. The experiences of Romberg and Bright, which show that direct irritation of the phrenic will not produce hiccough.

7. The existence of a perfect reflex-loop between the stomach and diaphragm, which more directly answers the purpose, separate from the function of respiration and beyond control of the patient.

8. It being influenced by the acts of deglutition or vomiting to a greater degree than by any respiratory efforts.—*Dublin Jour. Med. Sc.*

A Treatment for Round Worms.

Dr. P. Nicholson (*La Semaine Medicale*), commends the following:

1. Give santonine every day for a week only, for fear of poisoning the child.

2. Every evening on retiring, introduce into the rectum a suppository of the following composition:

℞ Ext. quassia.....6-18 cgms. (grs. j-ij¾)
Cocoa butter.....q. s.
Make ten such suppositories.

3. Apply morning and evening a little salve containing a small per cent. of colomel or the nitrate of mercury together with some extract of quassia.

4. Give from time to time the following rectal injection:

℞ Menthol.....6 cgms. (gr. j.)
Olive oil.....30 gms. (℥j)
Sufficient for one injection.

5. Cut the child's finger nails short and now and then plunge into an infusion of quassia to prevent auto-infection from scratching his anus and swallowing the ova. Finally, combat the constipation with calomel.

ARMY AND NAVY.

U. S. ARMY, FROM MARCH 26, 1893, TO APRIL 1, 1893.

Leave of absence for sixteen days, to take effect on or about April 1st, 1893, is granted First Lieutenant George D. De Shon, Assistant Surgeon U. S. Army, Fort D. A. Russell, Wyoming.

Leave of absence for two (2) months on Surgeon's certificate of disability with permission to leave the Department of the Platte, is granted Captain William G. Spencer, Assistant Surgeon U. S. Army.

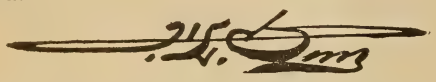
Leave of absence for one month with permission to apply for an extension of one month is granted Lieut. Colonel Charles C. Byrne, Deputy Surgeon General, U. S. Army Medical Director, Hdqrs. Dept. Columbia.

NEUROSINE is the Most Powerful Neurotic Attainable!

ALL Forms of Neuralgia is abated by the use of NEUROSINE. Relieves Completely Restlessness in Fevers, Producing Natural Sleep WITH NO DETRIMENTAL AFTER-EFFECTS.

Memphis, Tenn., Jan. 7, 1891.

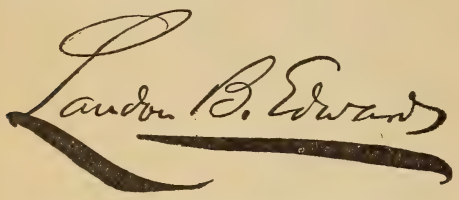
I have found entire satisfaction from the use of your Neurosine in cases of Neuralgia.



Dean Memphis Hospital Medical College.

Richmond, Va., Sept, 29, 1891.

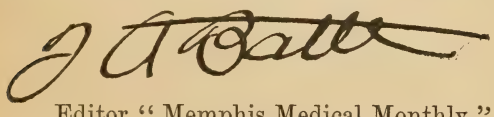
I prescribe Neurosine in the class of cases for which it is indicated, daily, and with satisfactory results. It relieves completely restlessness in fevers.



Editor "Virginia Medical Monthly."

Memphis, Tenn., Feb. 6, 1892.

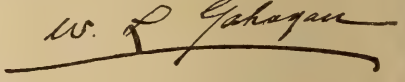
I take the opportunity to express my gratification at the happy results obtained from the use of Neurosine. It is certainly the best neuralgic remedy I have used and will ever be found among my prescriptions. I have tried it in two cases of trifacial neuralgia, after having tried some of our most powerful remedies, such as belladonna, opiates, quinine, gelsemium, arsenic, etc. None acted so well as Neurosine.



Editor "Memphis Medical Monthly."

Chattanooga, Tenn., Sept. 9, 1891.

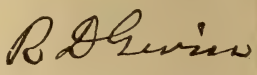
The completeness of the formula of Neurosine as displayed on the bottle at once attracted my attention. The sample was used and I must say the preparation has given better results and more universal satisfaction than any combination ever used by me. Have tried it in many nervous affections, in some it is a specific, in others a therapeutic agent of very great value.



Coroner Hamilton County.

McKenzie, Tenn., Feb. 12, 1891.

Neurosine had such a happy effect in a case of neuralgia or congestive headache in which I tried it, often having failed on other things of similiar nature. The case was one of long standing sick-headache of peculiar character. The lady, three days after confinement, without any fever, took severe headache. Neurosine relieved her immediately.



Stebbins, Va., March 8, 1892.

I have made fair trial of the Neurosine, and must say that it is in my hands the very finest neurotic I have ever used.

SAM'L HALES, M. D.

Ethridge, Tenn., March 23, 1892.

I gave Neurosine a fair trial in a case of neuralgia of the head and neck after a severe case of la grippe. It acted like a charm. Came up to all requirements.

C. D. HAMPTON, M. D.

Fourche Arcuault, Mo., March 18, 1892.

I sent about two tablespoonfuls of Neurosine to an old lady, aged 84 years; she had been complaining for some weeks with headache and neuralgic pains all over her body more or less. She took that small amount and has been quite free from pains ever since; went to church in a farm wagon 1½ miles, rough road, and is still free from pain, and sleeps and eats better. I am well pleased with it.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.
(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

Pil. Lady Webster.
(WM. R. WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.
(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ½ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.
(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES

DEAR DOCTOR:

I have met you before and trust you remember me pleasantly. I am doing my best to prove worthy the confidence you impose in me. If you have a bad case of Rheumatism, Gout, Gravel, or any form of Uric Acid poisoning, send for me. I am not a cure all, but I know how to assist you in getting these poisons out of the system. I adopt the "American idea" so that I may not be mixed up with my foreign rivals. American products for Americans is the popular sentiment. If you wish to know who my friends are, send me word. I have a list of the most eminent physicians in the world who are always glad to say a kind word for me. If you doubt my ability to control disease, I will do my best to convince you without charge. My offices are:

POSTURAL PATHOLOGY AND THERAPEUTICS IN OBSTETRICS AND GYNECOLOGY.*

WILLIAM B. DEWEES, A.M., M.D., Salina, Kansas.†

Hippocrates asserted that "accurate observation of facts, and correct generalization from them, forms the only rational basis of medicine," and so we are taught to-day. Grecian philology baptized man *anthropos*, the being with the upturned-heavenward-face. Throughout the animal kingdom the gift of bodily erectness is reserved to the human being alone. The dignity of the natural erect posture lies in the two following facts, namely: First, that by and through the primitive erect posture of his body, man is installed in his recognized lordship over the beast of the field; and second, that corporeal perpendicularity is both significative and comprehensive of physical healthfulness. Thus, it is manifest that the chief characteristic of anthroposophy is the philosophy of the erect posture.

Inasmuch as the prime object of addressing this august body of specialists is to present facts and to elicit truth by discussion in a given limited time, I must needs be brief. This object I will endeavor to fulfill by the light of general anatomy, common sense and experience, in calling your attention to the correct and the incorrect posture as related to uterine displacements.

Perpendicularity of the body is, mainly, the result of an equipoising of the upper half of the body upon the central part of the lumbar curve of the spine. This center in the lumbar curve is vertically supported on two equal bases—the femur heads— and by the aid of the mathematical diagrams (Figs. 1 and 2) is demonstrated to be the body's center of gravity. The body being equipoised upon this center, in both its axes, is literally pressed into symmetry by, and in the ratio of its own gravity. This balanced state of the perpendicular body is principally sustained by virtue of the normal tension of the spinal muscles, until the eqilibrium is broken by muscular or other disturbing force.

It will be observed, further, that the lumbar curve being in the body's centre of gravity, *i. e.*, vertically in line with the ankle and the ear, is not only the centre upon which is balanced the upper trunk transversely and antero-posteriorly, but that it is also at the same time the maintainer of pelvic obliquity. As such it is a fundamental point, since in the correct erect posture all decided movements of the upper trunk are derived from, and dependent upon, preceding opposite shifting of the lumbar spine. That is, neither bowing nor leaning backward can be ac-

*Read before the Western Association of Obstetricians and Gynecologists, Kansas City, Mo., December 27th, 1892.

†Vice-President of the Pan-American Medical Congress for Kansas; Ex-President of the Golden Belt Medical Society; Fellow of the American Association of Obstetricians and Gynecologists; Member of the Western Association of Obstetricians and Gynecologists, etc., etc., etc.

complished to a considerable degree without falling, unless the lumbar curve advances or retreats in the opposite direction. As the lumbar curve either advances or retreats from its central bearing, so will it, in the same ratio, increase or destroy pelvic obliquity by forcing the promontory of the sacrum to either ascend and advance, or retreat and descend, thereby compelling the pelvis to swing to a corresponding degree upon its base—the femur heads.

The philosophical conclusion of the aforesaid observation on the erect posture is, that the lumbar curve is the fundamental point and the spinal muscles the controlling source of both bodily symmetry and deformity. By a glance at Figs. 3, 4, 5 and 6, we have this truth fully demonstrated. Figs. 3 and 4 are photographs taken from life, and show typically the external form of the body in the correct (perpendicular) and the incorrect (stooping) erect postures as ordinarily observed in women. Figs. 5 and 6 represent, respectively, Figs. 3 and 4, showing their internal relations. As the model body, in both its external form and internal relations, is typically represented in the perpendicular and in the stooping postures, by Figs. 5 and 6, respectively, let us examine them somewhat in detail.

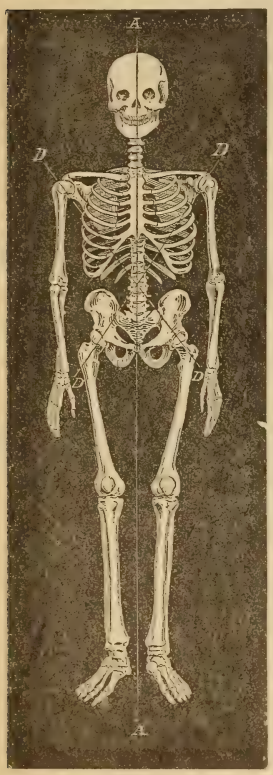

Fig. 1

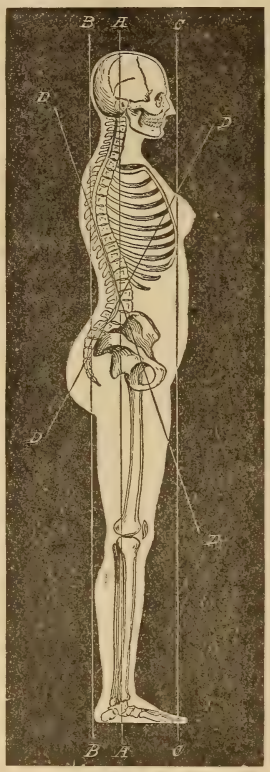

Fig. 2

Fig. 3

In the correct erect or perpendicular posture (Fig. 5), we notice that the body is well balanced with due symmetry and order prevailing throughout involving important, anatomical and physiological considerations. Here we notice:

First.—That, by and through the advanced lumbar curve, in vertical line with the ankle and

In the incorrect erect or stooping posture (Fig. 6) we notice that a very different state of both the outer form and the internal relations obtains. Symmetry and order are destroyed, and deformity and disorder prevail, involving important pathological and therapeutic considerations. Here we notice:

First.—That by and through the retreated lumbar curve, considerably behind the vertical

the ear, and the normal tension of the spinal muscles there is a consequent natural tensity of the pectoral and abdominal muscles, with the dorsal and lumbar curves of the spine, acting reciprocally as neutralizing equivalents.	line between the ankle and the ear, and the abnormal laxness of the spinal muscles, there is a consequent unnatural laxity of the pectoral and abdominal muscles. The head and feet remain intact, while the middle of the body—the lumbar axis—has shifted, thereby destroying the reciprocal equalizing neutralization of the dorsal and lumbar curves. Thus the influence of gravity alone has caused the droop, because the axis has receded.
SECOND.—That the pelvis is forced to remain so swung upon the femur heads as to occupy an obliqne position, *i. e.*, the promontory of the sacrum is elevated and advanced, the pubes retreated and depressed, and the plane of the pelvic cavity comparatively vertical. Thus the intra-pelvic organs occupy naturally a position very largely below and behind the sacral promontory, and are thereby very considerably sheltered from superincumbent weight.	SECOND.—That the pelvis is forced to be so swung upon the femur heads as to occupy a horizontal position, *i. e.*, the promontory of the sacrum is retreated and depressed, the pubes ascended and advanced, and the plane of the pelvic cavity rendered comparatively and unnaturally horizontal, with its axis in direct line of the depessing influence of visceral gravity. Thus the intra-pelvic organs now occupy an unnatural and unsheltered position, being exposed to all the evil consequences of superincumbent weight.
THIRD.—That the entire visceral weight of the abdominal organs rest mainly upon the pubes and the lower portion of the tense abdominal muscles, which maintain the viscera compactly elevated and coerced against the diaphragm, while the tense pectoral muscles advance and expand the chest. Hence there is a fullness of the chest together with largeness and rotundity at the hypochondres and the epigastrium with a firm state and trim form of the lower abdomen.	THIRD.—That the distance between the ensiform cartilage and the pubes has been greatly diminished, the pectoral and abdominal muscles have become lax, through which the viscera have lost their support and are now left to gravitate in the pelvis, upon the intra-pelvic organs and through them upon the intra-pelvic nerves, arteries, veins and lymphatics. Hence there is now a contracted chest together with a narrowed and retreated state at the hypochondres and epigastrium, while the hypogastric and iliac regions are unnaturally full and tumid—the inferior abdominal cavity being greatly enlarged antero-posteriorly.

Having seen plainly, in the light of physiological law, that the strong spinal and abdominal muscles are the chief conservators of the natural erect posture and the normal visceral bearings; and, that a lax state of these same muscles is the main influence in the production of the unnatural erect posture and uterine displacements, we will now take a comprehensive and critical observation of the status of each part chiefly concerned in this class of cases, with a view to successfully restoring them to health.

As the destruction of pelvic obliquity and visceral weight, are the prime factors in the production and maintenance of uterine displacements, it follows as a simple truth that, to remove this influence, the first indication is to restore the primitive trunkal and visceral bearings. This

Fig. 4

brings us to consider the most essential and fundamental therapeutic means, namely: How shall we best accomplish this first step to a radical cure? *Can it be accomplished by medicine?* Evidently impossible; so testify the facts in history.

Will it be secured by rest in the horizontal posture? Not in the premises; is the verdict of the most sagacious observers. *Is the purpose effected by exercise?* The consensus of opinion of the most careful practitioners proclaim in the negative; for in most cases the unnatural lax state is

not the result of inaction from indolence, but from exhaustion under untoward influences. Hence exercise would be a direct injury, inasmuch as in a depressed state of the uterus the influence of muscular effort is downward.

Shall we obtain it by pessaries? Both experience and physiological law substantiate the fact that, in the main, pessaries are prejudicial; as at best they can only serve to crowd the uterus upward against the depressing force of visceral gravity. *Do we find it fulfilled by abdominal supporters?* Most decidedly not; as the influence of their action is only compressing and depressing in that they fail to restore the normal pelvic obliquity and tensity of the spinal and abdominal muscles, and allow the lumbar spine to remain receded behind the true axis of the body.

Thus, is manifested in a concise manner, that the foregoing measures,—the usual means offered by our text books and works of reference—are inadequate and unadapted, either alone or conjoined, to the physiological and therapeutical requisites

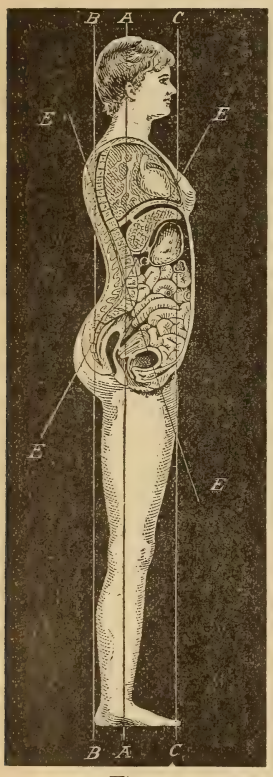

Fig. 5

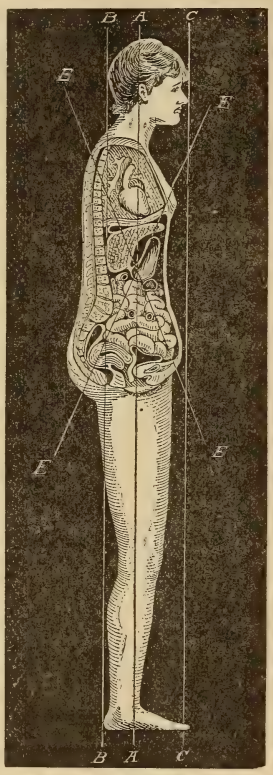

Fig. 6

Fig. 7

of a successful restoration of uterine displacements. Consequently, under the absolute necessity of obeying the physiological law, we find ourselves compelled to seek aid through some other means that will fulfill the therapeutic wants in this class of cases. The medium through which I have been enabled to successfully accomplish this desideratum, and to which I most confidently call your attention, is the ingenious contrivance shown in Fig. 7, manufactured by The Natural Body Brace Company of Salina, Kansas. Whenever I have properly applied this brace upon the body of a case of uterine displacement, wherein obliquity of the pelvis was destroyed by the lumbar curve being receded, together with a settled state of the upper trunk and a laxness of the abdominal muscles, I have invariably been successful in accomplishing a manifest immediate change from the unnatural to the natural erect posture, resulting in grateful expressions from the patient for the relief and comfort secured. The permanent good results obtained by the use of this

appliance in a large number of cases, have so convinced me of its valuable properties that I now look upon it as my chief reliance in the treatment of this class of cases. It will be specially noticed that its conjoined influence upon the lower abdomen and the pubes, as well as upon the lumbar spine and the shoulders, is such as to exert the requisite force to cause the upper half of the body, to become again equipoised upon the body's primitive centre of gravity in the lumbar curve, which is now again brought forward in the true axis of the body, while the pelvis is thereby forced to become so swung upon the femur heads as to occupy its natural oblique position. Thus by its bracing influence, the spinal, pectoral and abdominal muscles are aroused and aided to their normal tensity, whereby the primitive trunkal and visceral bearings alone can be restored and maintained.

In presenting these humble and mperfectly described observations on the philosophy of the erect posture and its influence as a therapeutic means in the rational treatment of uterine displacements for your kind consideration and discussion, I have earnestly endeavored to simply elevate a fundamental truth from the condition of a mere latent fact to that of an active principle; being at the same time mindful of the facts that "a good principle not rightly understood may prove as hurtful as a bad," and that "there is no falsity equal in mischief to that of truth when perverted and misapplied." As philosophy is ever true but may be misapplied, while established facts are always both true and scientific, the conclusion is warranted that any means whatsoever which most essentially aids in the foundation of a cure, should outweigh any opposing authority in our selection of remedies. It is the facts of important discoveries which usually appear first, and afterward their philosophy.

The truth to be kept foremost in mind is that there is such a thing as unerring language of nature in the human body, which can only be learned by observation. When this comes to be rightly understood it will greatly shorten our examinations, reduce our misjudgments and mistakes, gladden our hearts with more certain diagnostic and prescriptive criteria and elevate ourselves in our own eyes and in the eyes of suffering humanity.

DERMOIDS.*

JOSEPH PRICE, M. D., Philadelphia.

I have made this choice of tumor because the complications are about always present. Sometimes simple, but usually extensive and aggravated. Commonly there are very general adhesions to all surrounding structures or viscera, requiring cautious, painstaking surgery. They have a marked tendency to suppuration and inflammatory action; and in dealing with these cases there is needed a prolonged experience with suppurative forms of pelvic disease. Many of these cases are neglected, or go unrecognized until the patient demands relief at the hands of some specialist.

Dermoids are commonly small, their contents mixed and filthy. Occasionally fluid occurs in considerable quantities. In considering this subject I shall quote freely from that eminent pathologist, Mr. Bland Sutton, primarily for the reason that my own observations, the deductions of not a few experiences, are confirmed by his clear, concise, logical discussion of the subject. He has done much to help us out of our ignorance and confusion on the subject of dermoids. He has gone very far in settling for us their origin, the puzzling question of their pathology, the causes of development, their size, contents, etc.

He says: "The cysts which arise in connection with the ovary and parovarium may be conveniently arranged in three groups, according to the region in which they happen to arise:

"(1) Oöphoron, unilocular cysts, multilocular cysts, cystic corpora lutea, dermoids.

"(2) Paroöphoron, papillary (proliferous) cysts.

"(3) Parovarium, parovarian cysts,

*Read before the Obstetrical Society of Philadelphia.

pedunculated cysts hanging from the broad ligament.

"My first efforts were directed toward ascertaining the relation of dermoids to these three regions of the ovary. In all the examples of ovarian dermoids dissected for the purpose, it was easy to demonstrate that the parovarium was unconnected with them, but in several cases this structure differed in minor particulars from the usual arrangement of the tubules. Another interesting fact was the frequent association of malformation of the Fallopian tube with dermoids. In some cases there was an accessory abdominal ostium; in others the tube would have no abdominal opening whatever.

"These conditions have but little bearing on the pathology of ovarian dermoids, for they seem to be quite as frequently associated with other forms of ovarian cystomata. It now became necessary, seeing that ovarian dermoids have no connection with the parovarium, to ascertain as far as possible to which district of the ovary they belong. When a cyst attains a large size this task is an impossible one, but in dermoids of the size of a walnut, and sometimes when they are as large as an orange, it is easy to show that they originate in the oöphoron, and a series of observations carried out for this purpose has had the result of convincing me that ovarian dermoids arise in the same portion of the ovary as multilocular cystic tumors. These cysts arise in the Graafian follicles, and it is my intention to proceed to show that ovarian dermoids also arise in these follicles. Having localized the situation of ovarian dermoids to the oöphoron, the task became simple but laborious, for it involved a large amount of histological work.

"When an ordinary oöphorite cyst is compared with a typical dermoid the difference is very striking. In the simple non-dermoid ovarian cyst we find the interior lined by a single layer of flattened epithelium, and this may be difficult of detection. The dermoid, on the other hand, may present skin, hair, sweat and sebaceous glands, teeth and even a mamma.

Should the non-dermoid ovarian cyst be multilocular the individual cavities may, if not too large, present a membrana granulosa; in the dermoid the loculi are lined with skin, furnished with hair, etc.

"It may also be mentioned, as tending to show the close connection between ovarian glandular cysts and dermoids, that it is no unusual thing to find mucous cysts in the smaller loculi in the walls of dermoids. We must now proceed to consider the simplest form of an ovarian dermoid.

"If a cyst in the ovary presents the smallest piece of skin, furnished, perhaps, with only two or three hairs, its dermoid character is established. The presence of a tooth without any skin is sufficient. As a matter of fact every gradation may be traced from the membrana granulosa of an ovarian follicle to the glandular cutaneous lining of a dermoid. In some specimens the epithelial investment is indistinguishable from that lining an unilocular cyst. Yet in one small portion of the cyst wall a few hairs on a patch of skin place them in the category of dermoids.

"Thus far we know that ovarian dermoids resemble non-dermoid ovarian cysts in that they usually consist of one large cyst surrounded by numerous smaller ones. We have already seen that a multilocular cyst of the ovary may present only one tiny patch of dermoid tissue, though the tumor is composed of a multitude of cavities, great and small. There are good grounds for the belief that if all multilocular ovarian tumors were systematically examined patches of dermoid tissue in the cyst would be found to occur with very great frequency. Lastly, an ovarian dermoid may be multilocular, all its cavities presenting skin, hair, or teeth, or all three structures in the same cyst.

"Thus in the general disposition of the cavities, single, multiple and mixed, dermoids and non-dermoid ovarian cystomata are in agreement. The most highly-organized ovarian dermoids are those which contain a well-developed mammary gland capable of secreting a fluid resembling milk.

"In order to obtain teeth in a cyst lined with mucous membrane we need calcify some of the cellular projections, and a dermoid is the result. Calcific patches and cartilage are not peculiar to dermoids; they have been seen in non-dermoid ovarian cysts. Finally, although there are striking differences between simple ovarian cysts and complex dermoids, nevertheless the difference between a complex ovarian cyst and a simple der-

moid is practically *nil*, and, as a matter of fact, the glandular ovarian cysts are often structurally more complex than many dermoids, and I see no escape from the conclusion that *ovarian dermoids, like oöphoritic cysts in general, originate in Graafian follicles.*

"It must be borne in mind that a distinction exists between dermoids occurring in such situations as the angle of the orbit, tongue, neck, etc., and ovarian dermoids."

So interesting and important in our surgery is the subject of dermoids that we will collate the best of modern authority, this with a sense of certainty that too much light cannot be thrown upon a subject which has been, and is yet, involved in not a few doubts.

Pozzi, p, 100, Vol. II.

Mixed tumors, as well as dermoid cysts, often ossify; but a study of their structure emphasizes the interesting fact that the fragments of bone are not necessarily situated near the dermoid cyst, but may, indeed, be quite independent of them.

Pozzi, p. 121, Vol. II.

The frequency with which purely dermoid cysts are met in certain parts of the head and neck is well known; on the other hand, the complex tumors called teratomata are often met with at other points (sacral region, anterior mediastinum, palatine arch).

Pozzi, p. 121, Vol. II.

Velitz, of Budapest,* reports a curious case of dermoid cyst with a mamma. Woman, aged forty years, who had borne twelve children. Ovariotomy was performed for a dermoid cyst containing oily matter mixed with white hairs; upon the internal wall was found a sort of mamma as large as a child's fist; a little milk resembling colostrum was squeezed out from the nipple. The areola was pink, and surrounded by a circle of hairs.

Pozzi, p. 121, Vol. II.

In the Museum of Clinical Gynecology at Halle, there is a piece of a dermoid cyst taken from a goose, and containing several feathers.

Pozzi, p. 121, Vol. II.

Baumgarten, *Virchow's Arch. f. Path. Anat.*, Bd. CVII, 1887, p. 515. The finding of retinal epithelium has already been reported by Marchand, *Bresl. Arztl. Zeitschr.*, 1881, No. 21.

Pozzi, p. 121, Vol. II.

A. Fränkel, Ueber Dermoidcysten der Ovarian, und gleickzeitige Dermoide im Peritoneum, *Wiener Med. Wochenschr.*, 1883, No. 28, *et seq.*

Pozzi, p. 96, Vol. II.

They are usually small, but they may become voluminous by uniting with proligerous cysts, or even in consequence of acute inflammatory attack which suddenly increases their fluid contents. Though they may be long unrecognized, and perhaps revealed only by chance at the autopsy, as they begin (p. 97, Vol. II) to enlarge they approach, from a clinical point of view, the ordinary proligerous cysts that I have just described. Poupinel has gathered data in regard to forty-four cases where both ovaries were *transformed* into dermoid cysts. (See Thése de Paris, 1886, Poupinel.)

They are much less frequent than proligerous cysts.

Olshausen collected statistics of 2275 cases coming from a series of (operations) ovariotomies performed by Spencer Wells, Keith, Schroder, Krassowski, A. Martin, Billroth, C. v. Braun, Esmarck, Dohen and himself. Out of this number there were only eighty dermoid cysts (3.5 per cent). Their internal surface is covered with a membrane which looks like the skin, and which has a similar structure; we may see on it a corneous layer formed of several layers of flat and thin spheroidal cells, like those of the rete Malpighii.

Pozzi, p. 97, Vol. II.

A panniculus adiposus separates the dermic layer from the fibrous capsule of the cyst. Upon the surface of the derma are papillæ which may look like nipples, and some hairs which are inserted into hair follicles occasionally provided with a sebaceous gland; the latter were first demonstrated by Friedländer.

Sudoriparous glands are also found. The hairs whether free or implanted, are long, tawny, agglutinated together by sebaceous matter, and sometimes rolled into little balls.

Sebum, resembling the vernix caseosa, partly fills the cavity, and often forms small, isolated masses; it is sometimes oily in consistency, and contains many epithelial cells, cholesterin crystals, and fatty acids.

*Archiv. f. Path. Anat. und Phys. und Klin. Med. Bd. CIII. Heft 3.

Teeth and bones have been found in these cysts; bones are inserted in the wall, and more or less covered by the dermic layer (Pozzi, p. 98, Vol. II.); they are irregular in shape, usually flat, and formed of compact tissue; cartilage is present in small patches, which, according to Labbé and Verneuil, sometimes articulate by means of intervening fibrous bundles.

The teeth project into the cavity, and are often loosely inserted into alveoli formed of bony débris. They are never perfect in shape, and cannot be absolutely identified as incisors, canines or molars; the cement is usually absent.

Pozzi, p. 98, Vol. II.

Hollaender makes the interesting statement that the teeth are always placed with crowns sloping toward the median plane of the body, so that an examination of the cyst cavity will always determine the side of the body upon which it originated. As many as a hundred teeth have been found in one cyst (Schnabel).

Autenrieth describes a case where 300 teeth were taken out of a cyst which contained even more.

Some writers claim to have found carious teeth, but, as Lannelongue observes, Magitot is probably correct in thinking that this is not really caries, but a phenomenon of wear and absorption.

P. Ruge found in a dermoid cyst just below a bone which resembled the inferior maxillary with its molar teeth, a small mass which in form, size acinous structure had every appearance of a submaxillary gland.

Pozzi, p. 99, Vol. II.

Unstriped muscle fibres have been found in the dermic layer (Virchow); as to the striated fibres, Olshausen denies their existence, saying that where they are found the case is probably one of teratoma instead of dermoid cyst. In truth, many authorities confuse the two.

Pozzi, p. 99, Vol. II.

Cruveilhiér quotes a case where nails were found; Baumgarten reports a most remarkable case where the cyst, besides skin, hairs, and teeth, contained a body which resembled an eye, with a species of convex cornea and epithelium like that of the retina. There was also a mucous membrane similar to that of the intestines and stomach, and encephaloid nerve substance.

The presence of gray matter in dermoid cysts is a knotty point. In one case Virchow found gray matter, laminated as in the cerebellum; Key found some enclosed in a bony cavity; Rokitansky, in a species of capsule near a bone; other pathologists have, in exceptional cases, found nerve filaments supplying the teeth (Mahot and Legros.)

Pozzi, p. 100, Vol. II.

Besides these solid substances, dermoid cysts contain a milky fluid, in which are often chlosterin crystals.

Mixed tumors, formed by a combination of dermoid with other forms of ovarian cysts, have long been known (Lébert, 1857).

The subject has recently been studied by Pouperial (*Thése de Paris*, 1866), who states that in one and the same tumor we may find in closest union dermoid cysts and cysts with pavement epithelium, cubical ciliated, goblet, polymorphous cells, etc. More than this, in the same cystic cavity we may find the epidermis with its appendages (hairs, sebaceous and sudoriparous glands), and a lining of uniform or polymorphous epithelium. Finally, the interior lining of the cavity may be entirely formed of skin, which may, however, be incomplete. In some instances the cutaneous lining is found in a few places only of the dermoid cavity, and may be in the form of large papillæ, into which are implanted the hairs. The rest of the cyst wall is smooth and fibrous, or else looks more mucous than cutaneous.

Regret that thorough histological examinations of so-called dermoid tumors are rare. Were they more frequent it is probable that many cases of so-called dermoid cysts would be classed with mixed tumors. The fibrous stroma is usually formed of young connective tissue, of adult or myxomatous tissue. Yet, besides teeth which are produced from the ectoderm, and are met with only when there is a cutaneous lining, we find cartilaginous and bony tissue in the fibrous walls of mixed tumors. It may also be seen in tumors which possess no dermoid characteristics.

Poupinel reports an example of a mucoid cyst of the ovary, followed by the

appearance of cysts of the same nature all over the body; cartilaginous nodules found in its walls.

Both ovaries may be simultaneously affected. In that case, as in the case of unilateral ovarian tumors, combinations of every variety of cyst may occur. Every ovary may contain an epithelial mucoid tumor, with polymorphous epithelium or epithelium of one kind alone.

For instance, both cysts may be lined with ciliated epithelium (Brodowski, etc).

Pozzi, p. 101, Vol. II.

Oftentimes both ovaries are transformed into mixed tumors (Flesch, Neuman, Poupinel).

There may be a dermoid cyst upon one side and a mucoid cyst upon the other (Lebert, Young, Herchl, Mugge, etc.), or a mucoid cyst on one side and a mixed tumor on the other (Poupinel).

Pozzi, p. 101, Vol. II.

The question of *origin* of dermoid cysts is one of the most obscure points in general pathology.

The theory which ascribes them to *extra-uterine pregnancy* scarcely deserves mention, since they are often met with in children.

The theory of *diplogenesis* by fœtal inclusion is also inadmissible, and is at once disproved by the great number of teeth present.

The term *plastic heterotopia*, used by Lebert, is no explanation, but merely a name.

There are a few more tenable theories; that of *parthenogenesis*, which considers their formation due to a proliferation of germinating epithelial cells, is not satisfactory, because it fails to account for the presence of similar growths in other parts of the body where there is no epithelium.

The theory of *impaction*, although not beyond criticism, is on the whole the most satisfactory. According to this view, during intra-uterine existence certain portions of the blastoderm become impacted by pressure within the tissues, and develop there later, giving rise to an irregular formation of the normal tissues. Verneuil was the first to formulate this ingenious theory in regard to cysts of the branchial clefts of the neck and head (1883).

The demonstrations of his in regard to the axis cord, from which he claims that the genital organs are developed, assist us in understanding the complexity of the elements found in dermoid cysts of the ovary. The organs which are formed by all the layers of the blastoderm are the only ones which take part in the formation of the axis cord. It is impossible by dissection to identify the different germinative layers; we can easily imagine, therefore, that portions of tissue corresponding to the corneous layer, the medullary tube (ciliated epithelium), or the middle layer (muscle, bone), may become misplaced in the ovary as in the testicle. The impaction receives strong corroboration from these researches. (Olshausen, *Die Krankheiten der Ovarien*, Stuttgart, 1886, p. 404.

Lannelongue* adopts (impaction) it unreservedly. He calls attention, moreover, to the fact that the development of these tissues, foreign to the parts in which they are situated, brings about certain modifications in the structure of the latter, which add to the complexity of the abnormal growth. Perhaps this may explain the union of proliferating ovarian cysts to dermoid cysts, and the various transitional stages in these neoplasms. Still, Lannelongue does not entirely reject the idea of *diplogenesis* in cases where fœtal remains are found in cysts, which he terms fœtal cysts. He considers them to be combinations of cysts and double monsters; the cause giving rise to the production of the monster being intimately associated with that which determines the formation of the cyst. One or the other may predominate, according to the case; the higher we go in the series the more does the element of the monstrosity predominate, and the more does the cyst element tend to diminish and disappear. Thus, in the genesis of these tumors there are two factors to be considered: (1) the production of cystic cavities, and (2) the existence of a centre of supplementary development. To admit the existence of this (secondary) independent centre is to satisfactorily account for the complex character of these neoplasms, but it must be confessed that the admission creates problems quite as difficult of solution as those which it destroys.

*Traite des Kystes Congenitaux, Paris, 1886.

Thomas and Munde, p. 667.

In various parts of the body, orbit, floor of mouth, brain, eye, anterior mediastinum, lungs, mesentery, testicles, ovaries, peculiar cysts containing fat, teeth, hair, cholesterin, cartilage, bone are sometimes found. Their walls give evidence of the existence of sweat glands, sebaceous follicles, papillæ and an inverting epithelium, so that the microscopic appearance of the walls resembles closely that of skin. Many fanciful theories are given as to the origin of these peculiar growths. It is believed that they are the result of an irregular and eccentric development of the tissues of the fœtus during intra-uterine life. It was Lebert who advanced the theory that from the elements present spontaneous generation of a portion of skin occurs, and this being given we have, as Dr. Farre expresses it, "the basis out of which many of these products spring."

M. Pignè has analyzed eighteen cases with reference to the *period of life* at which they were found, with the following results:

5 existed in virgins under 12 years.
5 " " children from 6 months to 2 years.
4 " " the female fœtus at term.
3 " " fœtuses cast off at the eighth month.

Vary in size from a hen's egg to adult head, rarely larger. Are hard and generally globular. One ovary is usually affected and by only one tumor, but instances are on record where a single ovary contained several dermoids.

Thomas and Munde, p. 669.

Out of fifteen cases of dermoid cysts operated on by me, in three both ovaries were affected in this manner. One of these three women was pregnant at five months; from another, a single woman, 39 years old, I removed a switch of hair 2½ feet long, which after dissolution of fat contained in it by immersion in ether, it lengthened to 5½ feet.

Innocuous in themselves, not likely to increase rapidly or to attain great development, they sometimes set up very serious and even fatal disturbance by one of three methods: (1) suppuration and consequent abscess; (2) by perforation and discharge into peritonæum; (3) by cyst containing dermoid elements, secreting fluid and changing its character to that of a fluid tumor.

Out of 150 ovarian tumors removed by me, four were large cysts having as bases dermoids containing fat, hair and bone. In these cases the cysts containing the dermoid elements were not in communication with the large cysts filled with fluid colloid which constituted the mass of the tumor. In two cases the tumor was nearly removed when a cyst filled with fluid, fat, etc., was opened into. The large cysts appeared like ordinary multilocular cysts.

Often discovered by accident only. Often movable. Their tendency to inflame spontaneously.

Thomas and Munde, p. 670.

Produces pain and even elevation of temperature, which leads to their discovery, or their pedicle becomes twisted, or they are bruised accidentally.

Janvrin (of New York).

A bunch of hair protruding from rectum led to the discovery; patient pulled away hair; some years later her abdomen began to swell; two ovarian tumors diagnosed; on removal both proved to be dermoids, one of which had perforated into rectum.

Pelvic abscesses have been proven to owe origin to dermoids by hair, etc., escaping from sinus of supposed abscesses into vaginal vault (posterior). Should be removed by laparotomy as soon as discovered. Three chief periods in female life which seem to excite the dormant growth of dermoid tumors of ovary: (1) puberty; (2) martial relations; (3) pregnancy and parturition.

Greig Smith, p. 114

About one in ten ovarian tumors entirely or partially dermoid. Exact origin uncertian. Generally admitted that rudiments of all dermoids exist at birth, and that they remain quiescent indefinitely, or start into active growth at any period from or *before* birth to old age. Dermoid ovarian growths most frequently manifest themselves after puberty.

Greig Smith, p. 115.

Dermoid cysts is usually divided by septa into separate portions; and the contents may differ in various loculi.

The main cyst often contains a greasy, chocolate-colored fluid, while the others

are full of the characteristic sebaceous material.

Most striking contents are pieces of true bone, most frequently stunted alveolar processes.

Sebaceous follicles in the cyst-wall frequently attain to the dimensions of secondary cysts, and a similar development may take place in the sweat glands.

Malignant tumors have been found growing in dermoid cysts. (Bristol Infirmary; woman 59 years old; suppurating dermoid, in wall of which a solid sarcomatous growth, as large as a hen's egg. No secondary, malignant development in woman as yet.)

More than one observer has noted that malignant tumors of the abdominal cavity sometimes follow removal of dermoid cysts; no doubt the primary elements existed in the dermoid growths.

Both ovaries are liable to be diseased in a proportion of cases larger than in cystoma.

Ordinary glandular cystic disease is found to co-exist with dermoid cysts in a proportion of instances larger than would be likely if it were mere coincidence. Any casual connection between the two is not likely to be more than a stimulus to development started by increased vascular supply from the one which first began to take on diseased action.

Greig Smith, p. 116.

The *outer aspect* of a dermoid cyst is different from that of an ordinary cystoma. The glistening, pearly aspect of the latter is replaced by a muddy or opaque appearance, darker in color, sometimes approaching brown.

Adhesions are common in dermoid cysts, chiefly because they are liable to become inflamed.

Surgery of itself, in all abdominal work, to be successful must be clean, rapid, positive and direct of purpose. There should be no bargaining with chances, nothing begun in doubt, and it should be carried through to a finish with mathematical strictness in every detail. Rapid, deft surgery gives the best results throughout all surgery, special and general; it minimizes the harmful results of exposure and manipulation.

Short anæsthesia never waterlogs a patient. I am satisfied that a number of patients die from prolonged anæsthesia and the slow, hesitating and sluggish steps of the operation. Death will rarely follow a short anæsthesia and an operation shortened by a deft sweep and dextrous manipulation. We have rapidity of operation as an essential. Those who have had many surgical experiences, whether abdominal, pelvic or general, and have failed to consider time as an important element, have equally failed to carefully study many important phases in their surgical experiences and note the causes of their varying results. The rationalé of this must be plain to all. We have this one undisputed truth amid the many confusions the strong light of modern surgery has not yet driven out.

During these surgical procedures you cannot enjoy the delights of the aroma of a Wheeling stogie while you discuss a glass of Kentucky best and the advantages of the annexation of the Sandwich Islands. There should be the very perfection of cleanliness before, during and after operation, that extending to every detail and appliance and combined with the utmost simplicity of method. I would not place special stress upon any particular period of treatment, each and all should be regarded as having a peculiar importance—the one preliminary to, the one during, and that subsequent to, operation. So interwoven—interdependent—are the requirements of each that it would be difficult to give to one a distinctive importance over the other.

From the moment the patient comes under the surgeon's hands there begins that thoughtful, deliberate, skillful treatment, that conscientious exercise of sound surgical judgment, that attention to every phase and need of the case through all its periods until the patient passes from under his hands relieved or cured of her affliction. The neglect of the essential in any one period may be fatal in result, however skillful and successful the treatment through other periods.

There can be no distributing the responsibility so as to give more weight to one period than another. The entire freight of responsibility comes to you with the patient, and remains with you only to go out with her.

In every case the essentials of treatment, down to the most minute lines of detail, should be mentally mapped out, and these lines followed by the surgeon with

geometrical precision, and always with a ready and swift reserve at command for any and every masked trouble. If there are brilliant feats in abdominal surgery it is when an unsuspected or concealed enemy is uncovered and dealt with successfully. It is readiness for the trouble that lurks in ambush that goes to make up the successful surgeon. With our advances we will go on with our profitable discussion of essentials, reaching more uniformity of methods through that most determining of all influences—the death rate. I will in brief review some of the essentials, as I consider them from the standpoint of my experiences. Irrigation is an important essential, and should be scrupulously practiced to the point of great thoroughness in all cases where pus, clot and debris are found. The escape of the contents of any form of cystoma into the peritoneal cavity—the evacuated contents of dermoid tumors, pus tubes or ovarian abscesses, or of any variety of pelvic growths—should be followed by a thorough washing toilet. With each repeated experience I grow more confirmed in the conviction that drainage is an important step in assuring speedy recovery.

My experience with great numbers of angry troubles strengthens my confidence in drainage; of course, it is important to know when and how to use it. The man who tells us that he cannot remove the ovaries entire also tells that drainage is excessively used. Another tells us that drainage is harmful, and that he never operates for pus.

The resources of our surgery have been greatly added to by our improved instruments and materials. A large share of our surgical success is due to good instruments and pure materials, allied with trained, vigilant nursing. The best work is done with few and simple instruments and the best quality of pure material. For tying, silk, pure Chinese twist, the purest and best in quality and the finest and least possible, consistent with safety, should be used. Silk-worm gut, of strong, clean material, gives gratifying results. It is non-irritating, and forms a beautiful angle or box suture for the abdominal walls. There should be three or four to the inch, passed with care, including more aponeuritic and muscular wall than silk and peritonæum. We will speak of the character of the after-treatment without giving it a distinctive importance over any other period of the case. The required after-treatment is simple. Absolute rest, with patient on her back for thirty-six hours or longer, shifting position or restlessness not to be encouraged; clean, painstaking nursing; there should be relays of nurses, that the watch over the patient may be vigilant and unremitting. The nurse should be governed by the same keen sense of responsibility that should govern the surgeon. The patient's bowels should be kept soluble. No opiates at any time. Light and simple diet after the second day.

The triple alliance against good and successful surgery is delay, tinkering, which includes in its arsenal opium, and dirt.

Baron Rothschild's Business Maxims.

The elder Baron Rothschild had the walls of his bank placarded with the following curious maxims:

Carefully examine every detail of your business.

Be prompt in everything.

Take time to consider, and then decide quickly.

Dare to go forward.

Bear troubles patiently.

Be brave in the struggle of life.

Maintain your integrity as a sacred thing.

Never tell business lies.

Make no useless acquaintances.

Never try to appear something more than you are.

Pay your debts promptly.

Learn to risk your money at the right moment.

Shun strong liquor.

Employ your time well.

Do not reckon upon chance.

Be polite to everybody.

Never be discouraged.

Then work hard and you will be certain to suceeed.

Johnnie—"Tom, your mother says you are taking Cod Liver Oil. "What are you taking it for?"

Tom—"Medicine! did you think I was taking it for fun?"

COMMUNICATIONS.

THE ADMINISTRATION OF ETHER FOR SURGICAL OPERATIONS.

ELLISTON J. MORRIS, A. M., M. D., Philadelphia, Pa.

The death of Col. Shepard, during the administration of ether must awaken the profession to a renewed sense of the responsibility assumed in the use of any anæsthetic for any operation, no matter how slight. It is not the writer's purpose to criticise in any way the administrator of this unfortunate case, but simply to lay down a few simple rules for ether administration which have stood him in good stead in times past, and which he hopes may be of use to others.

It may be stated as an axiom that any agent which destroys sensibility is dangerous and should be carefully guarded in its use. The ideal anæsthetic, which will render the operation painless while the brain remains clear, and without danger to the patient, has not been discovered and probably never will be; but we can throw such safeguards around our administration of anæsthetics that the danger is reduced to a minimum. There will always remain a certain proportion of cases in which the death is absolutely unavoidable, and which can hardly be charged to the anæsthetic, though that may be the exciting cause. The writer can well remember an instance that occured to him. He had been asked to administer ether for an abdominal section; the operation was delayed a quarter of an hour for the arrival of the family physician, and in that time the patient had an overwhelming apoplexy and died. No ether had been given, but, had the death occurred during its administration, no one could have said that it was not the cause, directly or indirectly from increased tension on the blood vessels.

The XII Commandment, "Mind your own Business," is the golden rule for the anæsthetizer. He should have eyes, ears and hands for his own work alone, and to expect him to assist the operator in any way beyond giving his undivided attention to the ether, is to subject the patient to danger which should never be incurred. His eyes ought never to go below the patient's chest, and strict attention to the patient's condition, breathing, pulse and the depth of unconciousness will prevent the occurrence of those cases where "the surgeon nearly had a death on the table."

For the administration of ether, nothing is better than a soft towel, folded into a square of about eight inches, or several thicknesses of cheese cloth about the same size. By catching the folded towel at opposite sides it can be held in such a way as to form a cone giving room for the ether to vaporize above the patient's face. It is not the amount of ether poured on the towel, but the amount of ether vapor that the patient inhales that renders him unconscious, and hence the necessity for the space above the face for the vaporization of the ether. I have often seen the anæsthetizer hold the towel close down to the patient's face and pour on ether, wondering why the patient struggled and did not become unconscious, when raising the towel slightly would have remedied the matter. The folded towel has the advantage over every other form of ether inhaler in that it can be had in every house, no matter how humble, and is always clean. A fresh one can be substituted without trouble if the first one becomes soiled by vomit, which cannot be done with any form of inhaler. Usually the patent inhalers used in our hospitals, are foul from the vomit of many patients and it is almost an utter impossibility to keep them clean. The objection to the towel—that it requires more ether than the inhaler—is, to the writer's mind, more apparent than real and should not be allowed to have any weight in the matter.

Patients are often extremely nervous about the ether and dread it much more than the operation itself. If the anæsthetizer will begin its administration gradually, at first allowing plenty of air to reach the patient and thus avoiding the distressing irritation of the larynx, he will find that his patient falls into a quiet sleep, hardly knowing that unconsciousness is coming. A good plan with the very nervous is to place the towel over the face

dry, encouraging the patient to take deep inspirations, adding the ether, at first drop by drop, and increasing the amount as the patient becomes more used to its presence. The towel need not be removed from the face as the ether can be shaken between the folds. A few gentle encouraging words and the assurance that everything is all right, will to a great degree ward off the period of excitement.

The cough in its early stages is distressing and can be avoided by giving a few drops of fresh ether frequently, at the same time ordering the patient to take full inspirations. Vomiting will be avoided by directing that the patient have no breakfast on the morning of the operation or, if some nourishment must be given, it should be very light and consist entirely of liquids.

In spite of every precaution, the stage of excitement may be very severe and the patient require the combined strength of etherizer and nurse to keep him in bed. Particularly is this the case with those who are accustomed to use alcohol to excess, and who, it may be, have taken a "bracer" before the surgeon's arrival. Great care is to be taken in these cases that, on account of their struggles, they do not inhale more ether than is intended and suddenly plunge into the most profound stage. The etherizer should be on his guard to prevent such an occurrence by allowing the patient a little fresh air, and not pushing the ether too hard when the patient shows signs of relaxation.

The surgeon should be entirely prepared for the operation before the administration of ether is begun, so that when the patient is unconscious he can at once be placed on the table and the operation performed. Time is saved and the quantity of ether is lessened. Indeed, where the patient is in bad condition for the operation, he may often be put on the table before the stage of surgical anæsthesia is reached, in order that the surgeon may take advantage of the earliest moment at which he can commence the operation.

All through the operation the color of the patient and his respirations should be carefully observed. The peculiar bluish color, which comes at times, is a sign that the blood is not receiving oxygen enough and fresh air is urgently required. The breathing should be regular and deep as if the patient were asleep; snoring, or blowing breathing, with puffing out of the cheeks, shows that the centres of respiration are being invaded and calls for fresh air. The pulse cannot be taken as a guide as it will only show the amount of shock present.

It should be the aim of the anæsthetizer to keep the patient in a state between coma on the one hand and muscular resistance on the other. This is only to be attained by close watching of the patient. The ordinary rule of testing the degree of anæsthesia by the sensibility of the conjunctiva will answer in most instances, but in others will fail entirely. The same is true of the test by the reaction of the pupils to light. Perhaps the best rule is that mentioned in a recent editorial in THE MEDICAL AND SURGICAL REPORTER on the subject. It consists in noting the effect of the addition of a little fresh ether. If it causes no effort at swallowing on the part of the patient and no irritation of the throat, the anæsthesia is deep enough; but if such irritation be present ether can be given till it ceases. Beyond that point it is not safe to go.

During the administration of ether, and after the operation until the patient regains consciousness, the mouth and fauces should be kept clear of all mucus and vomit. It is hardly necessary to say that false teeth should be removed before the ether is administered. It is better that the anæsthetizer should personally inspect the patient's mouth and satisfy himself that there are no false teeth or other foreign body present. Patients are sometimes singularly averse to having the fact known that they wear false teeth and if simply asked the question will deny their ownership. If they are present they may drop down into the fauces and give annoyance if they do not lead to serious mischief. Snoring may be prevented by placing a thumb under the angle of the patient's jaw on each side and pressing it gently forward. The same can be accomplished by carrying the head into a state of extension. Snoring should, however, be watched as it is a valuable sign that the etherization has been pushed to its safe limit.

As has been said, the anæsthesia should be as short and quick as possible, and time can often be saved by withdrawing the ether as soon as the cutting part of the operation is completed and before the su-

tures are introduced. In the majority of cases the patient will not regain consciousness till the stitches have been placed and tied. The cardinal rule in all operations is the minimum amount of time and the least quantity of ether. Deaths after operation are often charged to shock where it were better to tell the truth and put the fatal blame where it belongs—to drowning with ether.

After the operation the anæsthetizer should remain with the patient till he has regained full consciousness, as cases are on record where the patient has been wheeled into a side room in the hospital, and choked to death because he had not consciousness enough to enable him to eject the accumulated mucus from his mouth. Should vomiting occur the best plan of treatment is to administer hot water as soon as the patient is able to swallow.

It has been the writer's good fortune never to have seen an ether death, but, where a fatal result is threatened, he would lower the patient's head and begin artificial respiration immediately, continuing it for hours if necessary, and administer strychnia hypodermically. Alcohol if given at all should be used with great caution.

It can easily be seen, therefore, that any old woman from the neighborhood cannot be safely trusted with the administration of ether. On no one, not even the operator himself, does the success of the operation depend more than on the anæsthetizer. In one sense he is like the engineer at the throttle. He must "give the machine" a little more steam climbing the grades and an ease-up on the descents, always keeping a lookout ahead for danger signals. When the cautionary signal comes he must be prompt to heed it. Accidents may come. Nature in rare instances may fail to show the red flag, but it will never be an excuse for the engineer controlling the anæsthetic, to plead "I did not see it till too late to apply the brake."

UTERINE FUNGOSITIES.

LEWIS SCHOOLER, Des Moines, Iowa.*

I have chosen this subject on account of its importance and the brief attention given to it by gynecological authors. What I will have to say will have little or no reference to text-book phraseology, and will little more than record my experience, which in no way, probably, differs from that of anyone present to-day.

But most of you may have been forcibly impressed by the length of time the growths have existed in many uteri, by the many diagnoses that have been made, and more than surprised that some of these have been made by men at whose hands we would have expected better things.

If the woman happens to be forty or more years of age, the most frequent diagnosis that I have heard of is change of life. This seems to be the cloak beneath which lurks most of the diseases to which womankind is liable.

That there may be eccentricities of menstruation at or about this period of female life, is more than probable, but that there is a continuous flow of blood for two or three years, to such an extent that the patient is unable to tell when the time for menstruation has arrived, I do not believe. And yet I have heard these stories and seen these cases by the score.

Many of our teachers in our colleges no doubt fail to give due prominence to the strictly practical and sometimes annoyingly common gynecological diseases.

The average medical student of the day is hardly satisfied with a gynecological clinic that does not afford a laparotomy, a hysterectomy or some other capital operation which not one in fifty of them will ever more than witness; and to these wishes too many of our teachers are liable to submit, unconsciously I grant, but nevertheless, it is a yielding that is detrimental to the interests of teacher and student alike, and, if it ended here, there would be little need of reform. But when we consider the suffering entailed upon helpless wo-

*Transactions of the Western Association of Obstetricians and Gynecologists.

men who have a right to expect relief at our hands, it assumes an entirely different aspect.

Fungosities may be malignant or benign. Most frequently they are of the latter variety, but the former are of sufficiently frequent occurrence that it behooves us to be constantly on our guard, and in some cases long observation and frequent examinations are necessary to determine the exact pathological condition, they being so near the border-line that it is difficult to say on which side they should be ranged.

The histological elements are of such a character that a microscopical examination will, it is true usually determine the character; provided the benign do not, as so frequently occurs in other growths, gradually become transformed into the malignant. The periodical congestions of the sexual organs at least conduces to a continuance of existing departures from normal conditions.

These growths are frequently little more than simple exuberant vegetations, which may or may not be complicated by the existence of polypi. When such complications exist a careless examiner may hastily conclude that the polypus is the only source of the hemorrhage.

In one of my own cases I found a polypus protruding from the cervix more than an inch, but a further investigation revealed vegetative growths in abundance in the uterine cavity. This patient had remained in her room two years, until she started on this trip of less than a hundred miles, and before its completion the hemorrhage became profuse. She had had instilled into her mind the change of life story,and was much surprised to hear that relief could be secured in any other way than by waiting until the change was complete.

In cases where hemorrhage is the symptom complained of, it is well to remember that all cases do not belong in this category. True malignancy, salpingitis, fibromata, and in rare cases perhaps disease of the vaso motor nervous system itself, must be considered as at least a possible cause and should be carefully eliminated, even though the fungosities are easily discovered, because of their possible co-existence.

The removal of one of these causes would have little or no effect upon the other, and the result would, although actually successful as far as it went, so far as complete relief is concerned, be a decided failure.

The prolific cause of these growths is no doubt in a majority of cases, abortions, miscarriages, etc.

That they occur in persons who have never been the subject of either of these conditions no one doubts, though frequently denials are made concerning these conditions that are not based upon the actual condition of affairs. In all cases where menstruation has become profuse and prolonged,I believe it is good practice to insist upon an examination for the purpose of ascertaining the true source of the disease. The hemorrhage is only a symptom and occurs under so many different conditions that its cause should always be diligently sought for. The diagnosis of the patient or that of other physicians, should not be accepted by a careful practitioner.

The diagnosis in these cases is not difficult. A female catheter with an eye near the end, a dull or sharp curette, or even an ear spoon can generally, owing to the relaxed condition of the uterus, be easily introduced into the uterine cavity and one or two of these growths secured.

This object attained, doubt no longer exists and the method to be pursued is plain.

The growths must be destroyed or removed.

Electrolysis has been used and highly recommended for this purpose, and I have no doubt of its efficacy in the hands of competent persons, but with this as with other procedures, the entire surface must be gone over thoroughly or recurrence is certain. For my part I have always been so uniformly successful with the sharp curette that I have never felt the need of other and more cumbersome appliances, none of which, in my estimation, will give as good results.

Curetting a uterine cavity is not a formidable procedure and yet I believe that many regard it too lightly. The introducing of any instrument into the uterine cavity is not devoid of danger under any and all circumstances. If they are strictly aseptic they are not dangerous, but where used without an anæsthetic they are productive of great discomfort in a

large majority of patients, so much so that in nervous or weak persons it is impossible to do thorough work, and where a patient is not under full control the difficulty of performing the operation aseptically is greatly augmented.

Where the vagina and the surrounding parts have been thoroughly and properly asepticised and the operation performed while the patient is under the influence of a general anæsthetic, the cavity can be more completely traversed by the curette, not even a solitary growth need be allowed to remain. The os uteri can be dilated sufficiently to admit of easy access, irrigation resorted to more effectively, and nothing impure need come in contact with either the genital tract, the instrument, or the hands of the operator, and no infection of the tubes or abscesses need follow. Neither will there be the liability to the disagreeable though not dangerous nervous chill which so frequently follows when the operation is performed without anæsthesia.

This phenomenon probably occurs more frequently in the hands of some operators than others. Not long ago a gentleman of large experience who seldom resorts to anæsthesia in these cases, told me that in his cases this operation had been so almost uniformly followed by a chill that he never omitted to warn the patient of its probable occurrence previous to beginning the operation. This has not been my experience though I have witnessed it occasionally.

The benefit derived from this operation in cases where fibroma exist is probably due to the alteration of the nutrition of the parts, as well as to removal of the proliferating cells of the thickened mucous membrane. And in malignant diseases the removal of the dead and decomposing material is always of advantage.

In conclusion I append the following deductions.

1st. Uterine fungosities are of rather frequent occurrence.

2d. Their existence is too frequently overlooked.

3d. When found to exist they should be thoroughly removed while the patient is under the influence of a general anæsthetic.

4th. The sharp curette is as nearly the ideal instrument for this purpose as are the knife and the saw in amputations.

WHAT IS THE SPHERE OF THE NASAL SPRAY?*

T. C. EVANS, M. D., Louisville, Ky.

In a recent discussion on this subject before the American Laryngological Association, Dr. Frank Bosworth, of New York, said: "I have recently removed the air-pump and spray apparatus from my office, and, I believe I have done better work since, than when I placed much dependence upon them." I am not yet ready to adopt such an extreme course as indicated by Dr. Bosworth. I find my spray a convenient method of cleansing the nasal cavities in atrophic rhinitis, in some cases of nasal syphilis and occasionally in the purulent diseases of the accessory sinuses. But, aside from these I do not think sprays accomplish any good; when we take into consideration its indiscriminate use I am convinced that rhinology in general, and our patients in particular, would be much better off if every man doing work in this line would follow the example of Dr. Bosworth. I believe but few men now claim to be able to remove genuine hypertrophies or deviations by local medication, but we all know that it is still a matter of common experience to see patients suffering from purely anatomical obstructions of the nose, who have been astringed, stimulated, disinfected, resolved, oiled and anointed according to the particular fancy of the individual member of the professional gauntlet which he has been so patiently running.

The treatment of diseased nasal mucous membrane by astringent and detergent sprays is such a pleasing, plausible kind of a placebo, has such a wonderfully potent moral effect on the patient, and has associated with it so many hopes and tra-

*Read before the Clinical Society of Louisville, Ky., March 7th, 1893.

ditions that many practitioners still cling to its use, knowing full well that their practice is not borne out either by theory or clinical facts.

For the first year and a-half after I began to devote special attention to diseases of the nasal cavities, I was so situated as to have abundant opportunities for observing the course of these affections under the use of medicated sprays, both in private and dispensary practice. I mention this simply to emphasize the fact that my skepticism in regard to this method of treatment is not born of prejudice, nor is it the product of any pre-conceived theory or notion, but is the legitimate child of disappointment. In spite of all my zeal and faith, after spraying my patients in season and out of season, I was quite forcibly impressed with the fact that all cases of nasal obstruction that came under my observation were almost hopelessly chronic; in fact the only limit set upon the time of treatment was the limit of the patient's perseverance.

Two years ago I read a paper before the Kentucky State Medical Society on "The Indiscriminate Use of the Nasal Spray," in which I endeavored to show the uselessness of this routine method of spraying, as well as to call attention to its pernicious effects, by depriving the patient of the relief that might be afforded by the more rational and radical methods of nasal surgery. In concluding that paper I said, "Taking it all in all, about the most charitable thing that can be said of the nasal spray, is that it rarely does harm, even in the hands of the inexperienced."

Now, after a more extended experience, I wish to reiterate what I then said in regard to the inefficiency of medicated sprays in the treatment of the obstructive diseases of the nose, and to modify that part of my concluding remarks in which I said, "they rarely do harm." All astringents, whether vegetable or mineral, sprayed into the anterior nares act as irritants—the degree of irritation depending upon the strength and temperature of the solution, the condition of the mucous membrane and the idiosyncrasy of the patient, but always acting as irritants in a greater or less degree. The alkaline sprays are perhaps less irritating; still I think it may be safely said that the spraying of any cold, watery solution into the anterior nares is injurious. I mean injurious, of course, in a limited sense, and do not wish to be understood as saying their use is followed by any very grave or marked symptoms, for experience has taught us that the nasal mucous membrane is an exceedingly hardy structure; that it endures the vicissitudes of climate, the vices of civilization as well as the blunders of medical science, if not uncomplainingly at least with a degree of toleration that shows it to be endowed with remarkable powers of resistance.

The use of sprays in cases of acute coryza prolongs and intensifies the attack. In chronic rhinitis they complicate matters by engrafting upon it an acute attack; they always make the patient exceedingly uncomfortable during and for some hours after the treatment. The substitution of vaseline and other petroleum products as a menstruum has done much to mitigate the evils of the aqueous solutions. First, because they are of themselves non-irritating; secondly, because they decrease or nullify the action of the drugs applied to the mucous membrane. But their use is open to serious objections aside from the fact that they are therapeutically inert. They arrest or at least greatly impair the respiratory functions of the nose by forming an impervious coating to its entire mucous surface; they prevent the giving off of heat; they prevent the exhalation of moisture; they prevent the exchange of gases that should normally take place in the nasal cavities—in short, this protecting of the nasal mucous membrane with vaseline, of which we have heard so much, simply means that we abolish the respiratory functions as long or often as we apply protection, so that the inspired air instead of reaching the larynx and lungs saturated with moisture and raised to a temperature approximating that of the blood, is cold and dry, as in buccal respiration. It is admitted even by their most zealous advocates that their prolonged use produces a condition very closely resembling atrophic rhinitis.

The history of nasal therapeutics shows that, sometimes at least, there is much in a name. The older writers laboring under a misapprehension both as to the anatomical structure and the function of the nose, classed all the disorders of this organ under the general name of "Catarrh."

To this name and not to any existing pathological condition, was due the general introduction and great reputation of medicated sprays.

It must be admitted that the spray is a most ingenious apparatus; that it affords a speedy, efficient and cleanly method of applying medicines to the whole of the nasal mucous membranes, but unfortunately for all concerned, we have not in the whole pharmacopœia a single medicine (cocaine perhaps excepted), of which we can say with any degree of assurance, that when so applied it will favorably influence either the course or duration of any of the obstructive diseases of the nasal cavities.

To sum it up briefly, I will say that the sphere of the nasal spray is an exceedingly limited one; that with the medicaments as commonly recommended in text books, its use in most conditions of the nose, is positively detrimental; that there are a few conditions where we find it convenient for cleansing purposes; that it is never curative; that those morbid conditions of the nasal passages which are amenable to treatment, are such as can be corrected or relieved by surgical means.

SOCIETY REPORTS.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of February 2, 1893.

"Dermoids," by Joseph Price, M. D. (See page 561).

ABSTRACT DISCUSSION.

Dr. W. Reynolds Wilson: In the limited experience that I have had in abdominal work, I find that I agree with Dr. Price in regard to irrigation. I think that it is very important that sterilized water should be used freely. In the Lying-in Charity, I have come to the conclusion that the free use of water, not only in abdominal work, but also in plastic work, is of great advantage. I think, also, that we should exercise great care in keeping the skin clean, so that the needle as it is carried through shall not be contaminated with material from the skin. If the skin is kept clean, if the suture material is kept constantly moistened with the aseptic solution—sterilized water—if the needle is kept free from clotted blood, and if the sponge or pad is frequently used, there will be no results from the introduction of septic material.

In plastic surgery the free use of water is also very important. A small stream of water will keep clots off the surface and keep the wound clean. I think it stands to reason that blood clotting on the surface of the wound, changing from the moist to the dry state, and going through the sticky stage, offers a field upon which any dirty material floating through the air can be deposited.

In the operations that I have done I have kept the surface of the skin perfectly clean. If there has been hemorrhage from an external artery, that should be checked, and if there is any blood on the skin it should be washed off. This is somewhat different from the modern surgical idea of a dry operation. How successful the dry operation is in general surgery I cannot say, but so far as gynecological surgery isconcerned I believe that water is useful.

In regard to the question of sponges or pads, I prefer sponges, because I believe that they can be made aseptic. They hold more water than pads, which can be readily expressed and the surface of the skin kept perfectly clean.

Dr. Howells: I have listened with a great deal of interest to Dr. Price's paper on this important subject of dermoid tumors, particularly from the fact that I have been seeing a good deal of his work for the past week or so, and must confess that I am thoroughly pleased with it. It has been my privilege to have been associated with Mr. Tait as pupil and assistant for the past six months, and I am conversant with his later methods, and I have been especially pleased to find that

Dr. Price is following the same lines as Mr. Tait.

In regard to the frequency of dermoids affecting both ovaries, one case comes to my memory in which both ovaries were removed during pregnancy, and each ovary was the seat of a dermoid tumor. Both ovaries were submitted to careful microscopical examination, and in neither could a trace of ovarian tissue be found. This is a curious fact, and points a moral. In the first place, here we had both ovaries apparently destroyed and still ovulation going on and fecundation taking place. It is a question whether this is not an argument in favor of the conservation of ovarian tissue in operation, and whether Polk's views have not good arguments back of them. If he finds a portion of the ovary in good order he leaves it and resects the diseased portion.

I was also interested in the question of irrigation, which is a very important one. I have seen operators remove neoplasms or ovaries, with escape of purulent fluid into the abdominal cavity, who for some reason have neglected to irrigate or wash out the abdominal cavity. In almost all these cases you get post-operative results of a disastrous and dangerous kind. It is often difficult to say where the dividing line lies. In removing a multilocular cyst some of the gelatinous, colloid material may escape into the abdominal cavity, and in some cases there are no bad consequences, while in others there will be secondary inflammation of the peritonæum. Mr. Tait's method in all doubtful cases is to irrigate, and he uses water freely, almost recklessly. He employs his small-sized trocar for irrigation. With this he thoroughly floods the abdominal cavity, moving the instrument among the viscera and removing all débris, Dr. Charles Martin, who has done most of Mr. Tait's operating for the past few months, says that if he had his way he would irrigate in about every case; that it is advisable to irrigate always. He says that he never knew it to do harm, but always good, and in many cases it decides the question of the life or death of the patient. Mr. Tait is not particular about using sterilized water. The water is simply taken from the tap of the house in which he is operating, and is raised to the proper temperature by the addition of boiling water, but is not properly speaking, sterilized.

The point raised with reference to the carrying of infective matter into the abdominal walls and causing suture abscesses is of importance. Mr. Savage always uses his sutures threaded at each end passes the needles from the peritoneal surface outward, so as to avoid introducing septic material from the skin surface.

Dr. E. W. Cushing, of Boston: I have had some experience with dermoids, and my views coincide with what has been said by Dr. Price and Dr. Howells. Especially is this so with reference to irrigation and drainage, which I use in the great majority of the cases on which I operate, and, as Dr. Martin has been quoted as saying, if I had my wishes I should put a drainage tube in nearly every case. In some operations which are perfectly simple it does not seem justifiable to use a drainage tube, but if a drainage tube were put in in every case some gentlemen would be surprised at the amount of bloody serum that would come from a case of the simplest description, as, for instance, the removal of the tubes and ovaries where there are no adhesions and the pedicle is tied off perfectly clean. In such cases I have seen free discharge. In this way we can appreciate the amount of blood and serum that is liable to come from the stitch holes, for under these circumstances it cannot come from anywhere else. I always feel safer when I use a drainage tube, and I have never seen any trouble from it, but I have lost a number of cases from failure to employ it.

In regard to dermoids, there is one point that I should like to emphasize, and that is that of all tumors they are most prone to degenerative and suppurative changes of the most disastrous character. The abundance of adhesions which these tumors have show old inflammation. We often have to operate when these patients are in bad condition. I may illustrate this by an account of a couple of cases seen within the last month. One was that of a lady who had had repeated attacks of peritonitis, with a history of abscesses forming and opening through the bowel. She had reached the last extremity of pain and suffering. I operated, and found a little suppurating dermoid imbedded in a mass of hardened tissue, communicating low down with the bowel. The bowel was so contracted, as I found by autopsy, that it would not admit the little finger. One ureter was entirely

cut off by cicatricial tissue, and the other seriously interfered with and dilated. I would suggest as a point for discussion the question whether or not the mortality is not greater in cases where the ureters are interfered with and the function of the kidneys cannot go on properly. This woman died with symptoms of obstruction of the bowel and sepsis. The patient was lost because the tumor had not been removed years before, when the first inflammatory symptoms occurred. All operating surgeons agree that in these cases death is not due to the necessities of the condition, but to the fact that the patient has not been operated on in time.

Day before yesterday I operated in a case with a similar history of repeated inflammatory attacks. The patient was in a bad condition, with a temperature of 102° or 103°, a pulse of 130 and signs of pus. There was a mass high up in the abdomen, and the pelvis had large masses in it. When I came to operate, I found difficulty in getting into the abdominal cavity. I finally got into a cavity from which a distinct fæcal odor came. This I washed out, and finally a hair escaped. I then knew what I had, and soon pulled out a "chignon" seven inches in length. The question then came up whether to remove the dermoid or leave it. I decided to remove it, which was done with great difficulty, as it was adherent to the intestines all around and to the abdominal wall. There was no pedicle. It had nothing to do with the ovary or uterus. There were the remains of what I took to be the urachus, and a large obliterated vessel. I then washed out and packed the cavity and went into the pelvis, where I found a dermoid of one ovary and a little tumor of the other ovary. I used a Mikulicz gauze drain and a glass drainage tube. These and other cases illustrate the necessity for early attention as soon as the diagnosis is made, and the danger of waiting until repeated attacks of pelvic inflammation have occurred.

Dr. B. F. Baer: I heartily subscribe to all that Dr. Price has said regarding the necessity for early operation and good surgery, and indorse what has been said about the question of time. Sufficient time should be taken to do the work well, whether five or forty-five minutes are required.

I find myself, however, in opposition to my friends concerning irrigation and drainage. As my experience grows I am more convinced that the drainage tube is employed to an unnecessary and excessive degree, and I wish to express myself emphatically in favor of the belief that irrigation and drainage are not necessary in 5 per cent. of cases, taking all classes of cases, from the most complicated to the simplest. I believe that I meet with as bad cases as it is possible to have, for I operate on every case, just as they come along, and I do not drain in 3 per cent. I have not used a drainage tube in operation for dermoid tumor within the last three years, and among the number several had suppurated. During that period I have not lost a case of dermoid tumor. The last one, operated on two weeks ago, contained two quarts of the ordinary material found in these growths, together with a bunch of hair. There were no adhesions in this case, and the contents were healthy. The incision was quite small, less than two inches, and a little of the fluid got into the abdominal cavity; but I did not irrigate. The cavity was clean after a little sponging, and I did not see, therefore, why I should use irrigation and thus consume a good deal of time unnecessarily—an element about the waste of which so much has just been said by the author of the paper—neither could I see why I should employ a drainage tube in that case. The patient has done perfectly well, and the temperature has not been above 99°.

Now, permit me to relate, by way of illustration, a case showing the opposite extreme. Several months ago a lady, who was thought to be suffering from malignant disease, was sent to me from Kansas. She had been ill for a year, was emaciated, anæmic and cachectic-looking. She suffered greatly from pressure upon bladder and rectum. The pelvis was full of an irregular, hard and semi-fluctuating mass, the lower portion of which extended downward, between the vagina and rectum, almost to the vaginal orifice. I thought the disease would prove to be ovarian papilloma. I found it to be a degenerating dermoid, full of decomposed pus. It was adherent to bowel, uterus and bladder, and had burrowed in every direction under the peritonæum and between the vagina and rectum. I literally had to dig the tumor out piecemeal

from between the latter organs. I irrigated in that case almost constantly during the dissection, and I would advise irrigation in such cases. I did not use drainage, however, even in this case; first, because the wall of the bowel was very thin, and there was the fæcal odor to which Dr. Cushing has referred, I therefore feared the occurrence of a rectal fistula from irritation of the tube. In the second place, I did not use drainage, because I had succeeded in removing all of the tumor, and had left the pelvis clean. I therefore regarded the patient as safer without the tube. The only fæcal fistulæ that have occurred in my practice happened during the period that I employed the drainage tube oftenest. It is a weak argument to say that those who have bad results from the tube do not take care of it properly. But, lastly, *a priori* reasoning and my experience had taught me that drainage could be avoided in this and similar cases. The patient recovered slowly, and went home in five weeks. I believe that she recovered better and safer than if I had used a drainage tube. In a case upon which I operated yesterday, a large quantity of old, disorganized blood poured out while I was separating adhesions, and some of it escaped into the pelvis. This lady had been ill for eighteen years with a tumor fixed behind the uterus—a hæmatomatous condition of the ovaries and Fallopian tubes. The adhesions to the bowel were close. After careful dissection I removed the masses. The contents were not fetid. I did not irrigate, and, of course did not drain. The patient is very well to-day, and I have no doubt she will recover without difficulty.

To still further show that drainage is unnecessary and therefore harmful, I will state that I have had one series of 148 consecutive completed ovariotomies (including the hysterectomies during that period), without a death; and of the last 200 operations there has been a mortality of less than 2 per cent. I think that in these 200 cases I have not used the drainage tube three times.

That Dr. Price's cases have recovered does not prove the necessity for the drainage tube, for my cases have recovered without it. My patients do better without drainage, and I am sure they are safer from complications and annoying sequelæ. I do not have high temperatures. The temperature is usually from 99° to 100°. I do not have septic temperatures.

We attain the ideal in surgery when we get primary healing without suppuration, and this can only be obtained by clean operation and closure of the wound.

Dr. Joseph Price: Dr. Wilson has given us an interesting discussion, and I am delighted that his practice hugs mine so closely. He has great faith in irrigation and water in gynecological and maternity work. There I agree with him heartily. In maternity work I believe in soap and water first, last and all the while. I believe it is as important to cleanse the mucous passages as the skin, and practice it most thoroughly; and as fortifying this subject of irrigation I will say that I have washed over 1200 maternity cases without a death from any cause. I have the longest period without a death of any maternity in the world. That is in keeping the patients two week before delivery and a month afterward. The importance of water in obstetrical and plastic work is as great as in abdominal work.

I agree with Dr. Wilson in regard to clots. Dr. Agnew taught that a clot was a foreign body, and that all bleeding should be sought for and checked.

The importance of skin cleansing is paramount in all surgery. If the skin of the abdomen is thoroughly cleansed for two days before section and your materials are clean, suture abscesses are exceptional. Allusion has been made to the importance of the dry treatment. This works as well in abdominal surgery as in plastic surgery. It is here that we have so much confusion in abdominal work. Dr. Baer has alluded to bad cases, and states that he practices the dry treatment with good results, but he has told us repeatedly that he does not operate on pus cases.

Dr. Baer: You are mistaken in regard to that.

Dr. Price: I can prove it from the records of the Society. The dry operation answers very well in the absence of dirt, filth, and pus, of universal adhesions and cheesy disorganization of surrounding structures. Where, for instance, there is destruction of the cæcum or colon above the cæcum, with removal of the perito-

neal coat and perforation, this disorganization extending from the cæcum to the vermiform, often amputating the appendix, which comes away with the specimen, with the ilium cheesy and disorganized, requiring stitches at one or more points, it is impossible to deal with these cases successfully without irrigation.

The question of speed. The paramount importance of rapid and short operations, the minimizing of every detail, that of anæsthesia, of exposure, of manipulation, is universally admitted. Some one has alluded to hurry. By rapid operation I do not mean hurry. Mr. Tait has repeatedly said that a hurried operation is a dangerous operation. You all remember that years ago, before the days of anæsthesia, operations were rapid; the operators were deft, they were dextrous. It was simply startling to see some of the older surgeons, to use a common expression, wipe off a leg. I saw Dr. Nathan R. Smith amputate my brother's leg in a minute and a half. He did it with one rapid sweep of the knife, and said, "Sam, the saw," and away went the bone. I have never seen such speed in surgery. I believe that I am the author of the expression "chronic surgery." Anæsthesia has encouraged the tendency to chronic surgery. Men hang over their operations. As a distinguished surgeon said to his class, "You will meet with difficulties, but you will have to wriggle through somehow or other." What I mean is that if you pick up a tumor with some friable adhesions, a gentle wipe with the sponge will remove them at once. It is not necessary to hang over it and dance about from point to point in doubt. If it is a clean tumor from a clean cavity, the result is clean, and you close the abdomen with three or four sutures without irrigation or drainage. I criticise hurry as much as does any one else. To stop to discuss points in pathology, histology or anatomy, and to demonstrate the various parts revealed, and thus occupy forty-five or fifty minutes, is a mistake, and not fair to the patient.

Allusion has been made to Dr. Polk. While it is fair to give full credit to this surgeon for his work, it must be remembered that Schroeder made a careful effort to save ovaries, cutting away from them small cystomata and saving a small healthy piece of ovary where healthy tubes remained. His results were good. Dr. Polk has championed this work. Dr. Fullerton has referred to two beautiful cases of this character. The women had suffered greatly, and had had the benefit of prolonged treatment before operation.

Dr. Howells has referred to Mr. Tait's use of his trocar in irrigation. This works very well, but it is of metal, and is a good conductor of heat. If the water is warm it will run the temperature of the metal up at once, and you will feel that it is too warm. Again, it has only the side openings. The rectal bougie, with three sets of perforations and a perforation at the end, makes a good flush and sprinkler. It irrigates laterally and at the extremity. It is surprising in using the trocar and funnel with two feet of hose, the quantity of filth, clot and débris of all sorts that can be washed out after these operations for pus, ruptured tubal pregnancy, suppurating dermoids—a tumor that is prone above all others to suppuration and inflammatory action.

In regard to mortality. Dr. Stewart asks for temperature charts and certificates. I shall not take time to speak about temperature charts, because I hold peculiar views in regard to them. The most beautiful demonstration as to the value of drainage tubes and irrigation can be made with a series of twelve or six cases. Take six dermoids with universal adhesions and six angry pus cases with universal adhesions requiring enucleation of the specimens. Flush and drain these cases and place them by the side of six simple ovariotomies with simple healthy adhesions and no discharge into the peritoneal cavity, and note the difference in the pulse and tongues of the two sets of cases for the following two or three days. The six washed cases will have the lowest temperature, the cleanest tongues, coolest skins and the slowest pulse, and will be bright and cheerful and reading magazines.

Dr. Cushing has alluded to the enormous discharge of serum. You will remember in Keith's book he tells how he used drainage tubes in hysterectomy, and the enormous quantity of blood and serum that escaped from these tubes. In one or two cases he incised the vaginal vault and turned out filthy fluid and clot in cases where he did not drain.

Some one has alluded to the necessity of educating the profession in regard to

the importance of promptitude. That is a part of our business here. It is our duty to educate the profession as to the importance of early surgical interference in cystomata, fibroids and the suppurative forms of pelvic disease. The London, Birmingham and Edinburgh surgeons boast that they have educated the profession to recognize the importance of early interference in cystomata. It is that only, with their surgical refinements, that has reduced the mortality to about *nil*. Dr. Bantock lost his fifty-first case in one series.

A word in regard to diagnosis. This is often alluded to and criticised. It is frequently difficult to say what a certain thing is, but we are usually able to say that it is one of two things, and very rarely are we wrong. That is quite sufficient. A few days ago I removed a huge kidney. I was satisfied before operation that it was either the left kidney or a huge cystoma. It pushed the uterus down and filled the abdomen with the exception of a small space high up on the right. From the history and physical characteristics I could not say that it was not a cystoma, although I felt satisfied that it was a kidney. It proved to be a kidney. The history extended back thirty-one years. The kidney had a stone in it and contained two or more gallons of dirty, muddy fluid.

Dr. Baer reported two cases. He says that one had no adhesions. Well, I scarcely know a surgeon doing abdominal surgery, no matter how enthusiastic he is over drainage, that would think of draining such a case. It is not difficult to define our position. I drain about 50 or 60 per cent. of my cases, but I sometimes do six consecutive operations without a drainage tube. In Kansas City I removed a large fibroid tumor, tore out both tubes and ovaries, but I did not drain, notwithstanding I had divested the pelvis of all peritoneum. It was not the safest or wisest thing to do, but the woman made a nice recovery, although she was a chronic inebriate and a Kansas City courtezan. Another case in the same city—one of tubal and ovarian disease, universal adhesions; a difficult enucleation was followed by irrigation and drainage. A speedy recovery.

THE CLINICAL SOCIETY OF LOUISVILLE.

Meeting of March 7th, 1893.

The President, Dr. I. N. Bloom, in the chair.

WHAT IS THE SPHERE OF THE NASAL SPRAY?

is the title of a paper presented by Dr. T. C. Evans (see page 573).

DISCUSSION.

Dr. Wm. Cheatham: I agree with nearly everything the essayist has said concerning the use of the spray in the treatment of nasal affection. However, I have not been able to dispense with it, especially in home practice, for the reason that I have never found anything to take its place. As a substitute in some cases I use the post-nasal syringe, but find very few patients who can use such an instrument on themselves; again I use the "feeding cup" as a douche for cleansing purposes, after any surgery of the interior of the nose. The objection to the spray in the first place is, that it is not thorough. When used anteriorly it will not reach one-half of the internal surface of the nose. Neither will the douche when used anteriorly. The internal anatomy of the nose is such that no medication used anteriorly reaches thoroughly all parts, so the only thorough way to treat the nose is from behind forwards, whether spray, douche or syringe is used.

In the treatment of laryngitis, for the spray, I have substituted the brush and the syringe; in atrophic rhinitis I scarcely ever use the spray, using the syringe.

Dr. Coomes (Visiting): I have listened with a great deal of interest to Dr. Evans' paper and much of what he has said, I think, is correct. But certainly the atomizer is an instrument that cannot be dispensed with, particularly as Dr. Cheatham says, in home practice. No doubt

there are many of these cases that would be better treated by surgical interference, first washing out carefully with either posterior or anterior nasal syringe, as it is now positively known that there are many diseases affecting the nasal cavities that we cannot cure in any other way; still I cannot agree that the atomizer is simply a placebo, but is an instrument for the purpose of carrying medicated fluids into the nose. The question of whether the nasal cavities can be thoroughly medicated by its use, is, of course, a debatable one. In other words, if the atomizer is properly directed high up into the nares all parts of the tissue will be reached. Of course with the atomizer we cannot flood the nasal cavities as can be done with the ordinary syringe. I do not think the atomizer should be attacked *because it is an atomizer*. There are other instruments used as a means of conveying fluids to the nasal cavities for the purpose of medication, that are no more effective as curative agents. I recognize the fact that there are numerous cases which I treated fifteen years ago, that I thought could be cured with the atomizer, that I know now were not and cannot be cured by this means; I know that nothing short of instrumental interference will ever cure them. There are other cases, of atrophic rhinitis for instance, where the parts are dry, andI know of nothing in the world that will so effectually moisten them as the atomizer. It is also valuable in cases of nose-bleed where there is a constant oozing; we often find cases where we cannot pack the nostril as patients will not tolerate it. I think the atomizer has been unduly assailed and that Bosworth — like a good many other men—will move it back into his office. As Dr. Cheatham says very few patients can use a post-nasal syringe; it is a somewhat dangerous instrument, if used by the patient it is very liable to cause strangulation and unless the pharynx is very well trained it is the exception for the post-nasal syringe to be tolerated.

So far as oil and grease are concerned for use in the nose, it is simply absurd. Of course I can understand where a patient has had an exceedingly sensitive nose a little medicated oil may be of benefit.

Dr. J. M. Ray: I am most freely in accord with the statements made by the essayist. Any one who will study the pathology of nose diseases, I think will come to the conclusion that very little benefit is to be derived from any form of medication by the spray or otherwise. I do not think in the paper Dr. Evans intended to attack the spray *per se*, but any form of medication to the nose, whether spray, syringe, douche, or otherwise. I do not think it is possible to cure any form of nose disease by the spray. It is of value as a cleansing agent but not as a curative agent.

The first paper I had the honor of reading before a Medical Society in this city, was on the subject of Chronic Nasal Diseases, and I made the statement at that time, that what we needed was more throat surgery and less throat doctoring. The longer I live the more I have reason to reiterate that statement. I believe that all cases of obstructive rhinitis require for their relief some form of surgical procedure. I do not think that any case of hypertrophic rhinitis could ever be cured by the spray. The disease is not in the mucous membrane; there is no interference with the secretions from the mucous membrane. The cases of so-called excessive secretion from the nose are simply the result of defective drainage; the secretions accumulate because of hypertrophy, and the secretions liberated all at once appear as an enormous quantity, within a short time.

I simply want to emphasize the fact that I do not believe any form of nasal medication applied in solution ever cured any case of chronic nose disease, whether applied by the atomizer, douche or any thing of the kind. We are often forced to wash out the nose, and as a cleansing agent I know of nothing better than the spray used anteriorly and posteriorly.

With reference to the use of oils in cases of acute rhinitis, I believe there neutral are cases in which oils sometimes act as a soothing application and is agreeable to the patient. Whether it cuts short the attack or not, I am unable to say. I heard a doctor friend remark that he had been suffering for a week from an acute attack of rhinitis, and was advised by a number of professional friends to use various forms of medication, every one of which had done harm. He said that he believed there was no form of local application that would cure a case of acute rhinitis. I am much of the same opinion. Take acute

rhinitis and the more you wash it out, especially with any form of aqueous solution, the more irritable becomes the mucous membrane; the more blood we draw to the part the more sensitive becomes the mucous membrane.

Dr. S. G. Dabney: In the main I agree with what Dr. Evans has said. The spray in my judgment is not of much value as a curative agent, except perhaps, in acute cases where it seems to have a pleasant, soothing effect. I hardly see how we can entirely dispense with the atomizer, not only in atrophic rhinitis but also in the hypertrophic form. Most modern pathologists now claim that hypertrophic rhinitis is due to some form of obstructive process and with each inspiration there is more or less vacuum created just back of the obstruction, the air not passing readily from before backward, being hindered by this obstruction, the partial vacuum so created causing distension of the blood vessels and consequent hypertrophy. Granting that this pathology be true, the treatment indicated would be a removal of the cause, and that means to remove the obstruction. I have very little to say upon the subject as I believe the ground has been very fully covered. The spray has been greatly abused in the past, because relied on as a curative agent; but I do not believe that we will dispense with it entirely in the future, as for cleansing purposes and especially for use at home it is valuable.

Dr. T. P. Satterwhite: I have used the atomizer for some years but have never seen a nasal cavity thoroughly cleansed by any form of spray. I do not suppose the quantity of liquid thrown in the form of spray into the nose, at any time would amount to over a dram or two. Where there is obstruction of the secretions I have always used the douche, but not to have any current to go through the nose with much force. This is the only form with which I have been able to thoroughly cleanse the nasal cavity.

Dr. T. C. Evans: I really feel very much flattered that the gentlemen present have discussed the paper as thoroughly as has been done, and feel gratified that most of them agree with me. Perhaps Dr. Coomes did not properly understand me: I quoted from an article by Dr. Bosworth, but stated that I had not gone to the extreme of having the atomizer removed from my office. I have found the spray very useful for cleansing purposes, but in cases of chronic obstruction of the nose I cannot see that it has done any good, and also I have very serious doubts about acute attacks being cut short. I am sure that they were not shortened any by use of aqueous solutions. I have seen a few cases that seemed to be made more comfortable and slightly benefited by cocaine early in the attack. I mentioned particularly in my paper that the most frequent form of medication to the nose was by application of the spray. What is true of the spray will also apply to other forms of nasal medication. I meant to say that all forms of local medication in the obstructive diseases of the nose is worse than useless.

STRICTURE OF THE TEAR DUCT.

Dr. Wm. Cheatham: I have recently had three cases of stricture of the tear duct which I want to mention: The first case, a young woman, has an obstruction of the tear duct with an abscess of the sac. I want especially to note that in two of the cases after inserting the probe I made an examination of the nose, which I have not done very much until recently, and found that the probe instead of entering the inferior meatus had penetrated along between the mucous membrane and the turbinated bone into the middle meatus; almost no force or violence was used in making this false passage.

Another case, child five years of age. I had treated this patient for stricture of the tear duct for four or five months; she had also been treated by several other physicians without relief. I had examined the nose several times and saw no special obstruction there. The tear duct seemed to be perfectly formed and there was evidently no stricture, still drainage could not be induced. Upon closer examination I discovered that the turbinated bone was pressed too close to the wing of the nose. Taking a strong pair of forceps and inserting them between the side of the nose and the turbinated bone with very little effort I lifted it into proper position and the child has had no further trouble. The whole difficulty was that the turbinated had grown too close to the side of the nose closing the passage. In correcting the position of the bone, I

relieved the child after it had been treated at least eight or nine months.

I want to make a point that it is very important to examine the nose in these cases, especially after you have used the probe, to see whether it has made a false passage as it did in the two cases mentioned, and to see if there is any obstruction in the nose at the lower end of the duct.

DISCUSSION.

Dr. J. M. Ray: It has been my experience that treatment of obstructions of the lachrymal apparatus is as a rule very unsatisfactory. I have tried nearly all forms of treatment that have been devised and the more I treat this trouble the more charry I become about slitting up the puncta and canaliculus. I believe if you slit up the puncta and canaliculus you destroy capillary attraction and do away with the muscular contraction in the circular muscular fibres in the walls of the canalicula and then all drainage that takes place from the eye must be simply gross drainage. I always make a point to examine the nose in these cases; sometimes I have been able to discover the probe in the nose, in others have been unable to find it. I am treating a case now of chronic obstruction in the lachrymo-nasal duct. I can pass a probe through the duct into what I presume is the nose, and the nose will bleed, then looking into the nose I am unable to find the probe. I put cocaine into the nose contracting the turbinated and passed the probe to see if I could feel it—I was able to get the metallic click but could not see it.

I believe if you once start in with these cases, the best thing to do is to open up the duct well into the sac and thus get gross drainage; further, that the best way to do this is to take the lachrymal knife and slit well into the sac, pass it into the nose and cut the stricture, then turn the knife and bring it out to be sure that the stricture is cut; then by continued passage of the probe afterward see that it is kept open. There is no doubt that a great many of these cases are accompanied by nose disease, hypertrophy or thickening of the turbinated; therefore I am in the habit of examining the nose to see if the turbinated is not misplaced in any way. I believe that the few cases that I have seen completely cured have been cured in the manner above described.

Dr. Coomes: I never tell a patient that comes to me with obstruction of the nasal duct that relief can be assured in any given time; it may be in six months, six years, or they may get relief in one month. I think in the majority of these cases the trouble will be found to be stricture, and it is absolutely necessary to secure thorough drainage. Occasionally I have found stricture in two or three places. Like Dr. Ray I have run across obstinate cases where I have failed to get relief notwithstanding the fact that I have slit up the canaliculus, upper and lower, making a free opening. I think this is the best method of treatment, as in that way we get free drainage.

Dr. Wm. Cheatham: My idea in reporting the two cases was to show how easily a false passage might be made, the probe just slipping along between the mucous membrane and inside the turbinated bone, no more force being used than when the probe passes through the natural opening. I believe the latest authorities agree that the tears are not carried by capillary attraction at all. If stricture exists in the nasal duct I think it should be located just as would be done in the urethra. Suppose you have a stricture in the upper part of the tear duct, what is the use of running a knife through into the nose? With a stricture in the upper part of the tear duct I fail to see the occasion for using the knife. It seems to me the proper thing to do would be to use the probe and dilate it thoroughly.

CASE OF SYPHILIS AND TYPHOID FEVER.

Dr. J. M. Krim: Six weeks ago I was called to see a case that has been under treatment for secondary syphilis, having all the symptoms usually present in such cases. I found the patient suffering from an attack of typhoid fever, and four weeks after he came under my observation the eruption existing prior to the development of typhoid fever entirely disappeared. The enlarged glands grew smaller, and he has now in the sixth week, not a symptom of secondary condition existing. He was not under treatment more than ten days for secondary syphilis, and certainly the treatment he received in this time could not have been sufficient to cause disappearance of the syphilitic symptoms. I simply want to

ask the members if they have ever seen a case where the eruption disappeared in this way, and whether it will return again.

DISCUSSION.

Dr. I. N. Bloom: It is not unusual for eruptions to disappear during an acute disease, and as a rule recur after the acute disease has passed off. In this case, however, the eruption had already lasted three weeks, which is as long a time as it usually remains. The most interesting feature is the disappearance of the enlarged glands. I never give medicines in cases of syphilis until the secondary symptoms are manifest. I have known syphilides to disappear in three or four days before medicines given could possibly have had any effect. Then again I have seen papular and pustular syphilides last two, four and five weeks and longer under rigid treatment.

LATERAL DISLOCATION OF ELBOW; CHILD AGED NINE YEARS.

Dr. A. M. Vance: I would like to mention a case of dislocation of the elbow-joint in a girl nine years of age, the second case of lateral dislocation of the elbow I have ever seen where the ulna and radius were carried entirely outside of the humerus, reduction being very difficult. In the first case, which was a patient about the same age, treatment was instituted for fracture and reduction was never brought about. In the last case referred to, I believe the difficulty was from the biceps tendon, it in some way preventing the bones remaining in position after they were replaced by great force. I finally, however, reduced it and the subsequent history is that the whole arm is greatly swollen and the child has suffered a great deal from the traumatism due, undoubtedly, to the efforts at reduction. It is the second case I have ever seen, and I believe that dislocation laterally of the elbow is very rare. There was no fracture in this case.

EPILEPTIC SEIZURES DURING TONSILLOTOMY.

Dr. T. C. Evans: About two weeks ago I operated on a patient, removing a very small piece of tonsil. I applied with a cotton carrier a small quantity of four per cent. solution of cocaine, and proceeded to pull the tonsil up with forceps and clip off the piece with a pair of scissors. The patient did not seem to suffer any pain and there were no symptoms of syncope. Without any evidence of being sick—no whiteness around the mouth—the patient simply dropped out of the chair, and would have fallen on the floor had I not caught him. I laid him on the floor thinking that it was simply a case of fainting. But he had a very distinct convulsion and I proceeded as quickly as possible to get some whiskey; by the time I had gotten the whiskey to him he had regained consciousness.

The point that struck me was that it might be a case of cocaine poisoning. As he recovered so quickly I concluded that this could hardly be the case and inquired into his previous history. I asked him first if he ever had a fainting spell before, and he told me that he had and seemed rather disgusted with himself that he should have gotten sick in my office. I inquired into the history a little further and learned that on one occasion he had been sitting in a chair reading and had one of these attacks, simply falling out of his chair on the floor, so I concluded I had just happened to operate at the time he had one of these epileptic seizures.

DISCUSSION.

Dr. Wm. Cheatham: I think Dr. Evans' conclusion of epileptic seizure is probably the correct one.

Dr. A. M. Vance: My experience is that people often topple out of the operating chair without any cocaine, without anything except a minor surgical procedure. I had a patient faint to-day while the instruments were being prepared for a minor operation. I can recall several cases where fainting has followed the introduction of the hypodermic syringe, there being no history of epilepsy or anything of that kind. However, in Dr. Evans' case the history points very strongly to the fact that it was epilepsy.

Dr. Coomes: I have seen several cases of cocaine poisoning, and my observation is that it sometimes takes a very little cocaine to produce a decided impression.

Dr. A. M. Vance: I believe that a great many of the men who have written upon the subject agree that cocaine, when used about the head, has a much more

powerful effect than anywhere else. My experience is that this product is absorbed more rapidly by the mucous membranes than it will be when applied to cut surfaces. When a tourniquet can be used I believe that cocaine can be employed *ad libitum*, but in other cases it is sometimes attended with considerable danger. I remember using in one case, where operation was done for an epulis on the upper jaw, twenty-nine grains of cocaine in solution—the operation lasting nearly four hours. I believe the reason this patient did not die of cocaine poisoning was that the blood was continually washing it away. This is the greatest amount of cocaine I have ever used in one case. For a number of years I employed a four per cent. solution, but now use a six per cent. In the case referred to where such an enormous quantity was used, the patient absolutely refused to take chloroform, owing to her having been operated upon some years previously in Virginia and nearly dying from the effect of the anæsthetic. She recovered from the operation and now wears artificial teeth, the excrescence never having returned.

I have had no trouble in the use of cocaine since the first few months' experience, invariably giving whiskey beforehand.

CORRESPONDENCE.

PHILADELPHIA—THE MEDICAL AND SURGICAL CENTRE OF AMERICA.

To Editor of Med. and Surg. Reporter:

Sir:—Philadelphia is no less famous for great physicians and surgeons than for men of preeminence in other lines.

New York has been thought by many to equal, and even to excel Philadelphia, and of late, Chicago aspires to share the prominence of these cities as medical centres.

We believe, yes, realize that general surgery here is not one iota inferior to New York or continental surgery. How could Philadelphia lag behind with its incomparable list of illustrious teachers and workers of the past linked to the present by such names as Agnew, Gross, Levis or Meigs? Morton, Deaver, Keen, Roberts, Ashurst, White, and many others in all respects their peers,—these men, inspired by professional zeal and ambition, with natural talent developed by special training and hard labor, maintain general surgery in that high state of excellency not to be surpassed on either continent.

No higher compliment can be paid the graduate in medicine than having merited and obtained a diploma from one of the medical schools of this city. And to-day, in the schools of this city, more than two thousand students are matriculated in medicine alone,—drawn from Canada to South America, and from the Atlantic Ocean to the Pacific.

Philadelphia was among the first to demand a higher standard of medical education, and to establish it by requiring a three, and now a four year's course of study, with terms of seven to nine months each year, and a demonstration of proficiency before graduation.

For *post graduate* work it can be truly said that Philadelphia excels, and, all the year around, physicians are here preparing themselves for greater achievements in general practice and surgery, or in some specialty.

For Post Graduates the Polyclinic was organized and endowed several years ago, and to-day, is an honor and an ornament to the American people. The teachers are men of ability, great experience, wisdom and are the ablest of clinicians.

The physicians of Philadelphia have no "dude airs" or "red tape regalia" to present, to weary your patience or consume your valuable time, nor, do they consume your time by telling of their European trips, or what Sir James Paget, Landolt, Von Bergman, Martin, Sir Lenox Brown, Keith, Bantock, or Tait said about them, or of ovations received. But they prove conclusively that on their foreign trips their time was not occupied

in paying respects to sour krout, limberger and lager beer.

Their manner of teaching is simple and easy, yet grand and beautiful, and you are at once convinced of the profundity of their knowledge, high scientific attainments, remarkable courtesy and gentlemanly bearing. One is always delighted to return here, and when you have remained your allotted time, either in Post Graduate work at Polyclinic or with some specialist, you are loath to leave, and separation from such illustrious lights is indeed painful, whether you are a student in general medicine or surgery, ophthalmology, rhinology, otology, laryngology, genito-urinary, rectal, abdominal and pelvic surgery, or gynecology, dermatology, or obstetrics. You are allowed to examine, make diagnosis, prescribe and treat patients in each respective branch or specialty, and to make the refinements in diagnosis, treatment and technique of operations and minutiæ of handling instruments a part of self. And when each one returns home to his former field or seeks a new location, he goes forth a practical and competent specialist, able to reflect honor and credit to this great medical and surgical centre.

Nothing has been said about laboratory work at the Polyclinic, from the fact that the students at the Polyclinic have been general practitioners five, ten or fifteen years, and are good first class men who have succeeded in general work, been hard students and close observers, and have had, as a rule, previous training in histology, pathology, bacteriology and microscopy. Yet those who desire such instruction can obtain in Philadelphia as good as can be had on the continent. The Polyclinic has already reached a high state of perfection, yet there will be certain additions made that will very materially enhance the work and teachings, and be of inestimable benefit to both faculty and matriculants.

The writer has been more interested in ophthalmology at the Polyclinic than any other branch of medicine. He is proud of the course, and deems it one of earth's greatest blessings to have been a student of so distinguished and able tutors as Professors S. D. Risley, Edward Jackson and George E. de Schweinitz.

This letter would be incomplete if reference was not made to the two illustrious abdominal and pelvic surgeons of Philadelphia, viz: Drs. Joseph and Mordacai Price, who have a private hospital at 241 N. 18th Street with capacity for ninety patients. This institution has averaged forty to forty-five private operations for each of the months that I know of. Here the writer has seen the most difficult, painstaking and heroic abdominal and pelvic operations done in surgery. The courage, dexterity, rare judgment, precision, skill and almost mathematical certainty of recovery of patients is simply marvelous. These surgeons do what nature cannot do, they remove the offending growths or lesions under aseptic precautions, quick surgery, short anæsthesia, perfect hemostasis, minimum of shock, practical nursing reduced to a science, and perfect rest. Nurses are so well trained that they know the various steps of different operations, can hand the needed instrument at the right time to the operator without a word from him, the expressions of his face indicating the steps anticipated by the nurse. Besides the nurses can handle anæsthetics, hemostats and drainage tubes with such a skillful degree of accuracy, that some who claim to be abdominal surgeons might draw lessons from them. Dr. Price does not irrigate and use drainage in many cases because it is not necessary. But there are cases where irrigation and drainage are demanded and highly essential. These surgeons have the bulk of their work in cases demanding heroic surgery as a conservative, *dernier*, radical and thorough life-saving measure. Many patients have been previously dallied and tinkered with by the minor gynecologists, through office *rapid dilatation* and *curetting*. From the number of physicians of the North, South and West, as well as from the city, who daily attend Dr. Price's operations, one is convinced that the Prices are in themselves a whole faculty in abdominal and pelvic surgery.

It is with much pleasure that the writer refers to some brilliant surgical operations done at the Medico-Chirurgical Hospital by Dr. Ashton, whose courtesy, hospitality and exceeding kindness have made a grateful and lasting impression. He is a rapid operator and in him chronic surgery is not known or recognized by the spectator.

Another great advantage in taking post-

graduate courses here, is the various medical, surgical and pathological societies to which you are invited several nights in each week. Here you see, meet and listen to other professional giants not members of the faculties of the different schools.

Any physician contemplating a general or special course should keep his eye on Philadelphia and the Polyclinic. Physicians and surgeons here treat strangers and visiting physicians and students of the Polyclinic with the most marked courtesy and consideration, invite them to see their operations and clinics, and make life as pleasant as a sojourner could wish. Physicians should consider it quite a favor and a compliment to get to visit and witness the operations in abdominal and pelvic surgery, and demonstrations of pathological specimens after operation, at Dr. Price's private hospital. Dr. Price always demonstrates the pathological specimens, showing the need and necessity of a surgical operation. Having been associated with Dr. Price three months, one month in 1889 and two months this last winter, seeing his work daily, I am prepared to state that he operates for pathological lesions and finds them. His surgery is conservative for nothing else would save the patient. His conservatism is doing the right thing at the right time, the best that could be done for each patient.

Two operations at the Polyclinic for larcerated perineum, and two for the same at the Gynæcean Hospital, were decided successes.

Dr. J. M. Baldy proved his skill in two intra-vaginal hysterectomies in which cancer had begun to develop in the body of the uterus but could not be detected, demonstrating the surgical meaning of a uterine leucorrhœa or metro-staxis after the menopause, as pathognomonic of cancer, and early surgical interference and removal of the offending organ before constitutional infection.

One of the boldest and most rapid abdominal operators is Dr. Baer. He showed the writer many courtesies, is an instructive lecturer, a good diagnostician, claims to not use the drainage tube more than two or three times in two hundred cases of cœliotomy, resorts to the dry treatment of the peritoneal cavity. He removed a fibroid of tube and ovary, with numerous strong adhesions, without drainage or irrigation, with an after temperature 100° and pulse 96, and, anticipating hemorrhage several hours later, reopened abdomen. He teaches gynecology and physical diagnosis of pelvic organs with force and precision. Dr. Baer demonstrated his operation of tying or shortening the broad and round ligaments for prolapsed uteri through abdominal section. He operated on a woman with prolapsus uteri, tied off the broad ligaments, thereby shortening them, also the round ligaments; replaced the womb in its normal position, and ten days later did operations for cystocele and rectocele, getting primary union and giving a new appearance to the genitalia,—that of a virgin ostium. Dr. Baer also demonstrated several times his method of intra-peritoneal hysterectomy and tying of the uterine arteries, dispensing with the *serre noud*, and coaptating the peritoneal layers (anterior and posterior) over the cervical stump, hermetically closing it, cutting off connection between the peritoneal cavity and vagina.

It is self-evident that students and post-graduates have advantages in Philadelphia not to be had in other large cities.

While Polyclinic schools and hospitals are of great benefit to the profession and to humanity, there should be restrictions around every one, viz: The matriculant should be endorsed by his county, district or state society, and should present his credentials before matriculating, take an oath that he is not going into quackery after completing his course, and register in the general or special branch he desires to devote his time and attention to. No man, physician even, with many years general practice can be a specialist in three or six weeks without long previous study, training and experience in some special line. Yet there are physicians who have seen one or two operations in abdominal surgery by some skilled surgeon, an adenoid vegetation removed from vault, or enucleation or cataract extraction, and returning home, have announced in the weekly or daily newspapers their cards—"Specialists in Gynecology, diseases of nose and throat and eye." The great evil likely to attend Polyclinic teaching is the manufacture of charletans. Therefore let every post-graduate Medical and Surgical College have restrictions to suppress and prevent quackery, and not aid in their development.

J. G. Carpenter, M. D.

Stanford, Ky.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 15TH, 1893.

EDITORIAL.

SUPPORT THE MEDICAL EXAMINERS' BILL.

Every physician who appreciates the danger to the community of allowing ignorant persons to practice medicine, should give earnest support to the Medical Bill now before the Senate of Pennsylvania. Efficient assistance will be given the Legislative Committee of the State Medical Society, if every reader of THE REPORTER will at once write to the Senator representing his district, asking his vote for the bill. The bill originally introduced in the Legislature has been modified so that it more nearly resembles the New York law than it did at first.

The well-known surgeon of Brooklyn, Dr. L. S. Pilcher, stated in his recent presidential address at Albany, that the New York law was exceedingly satisfactory; and Dr. D. B. St. John Roosa, President of the New York Academy of Medicine, gives similar testimony as to the efficiency of this law in elevating professional standards of education and protecting the people from ignorant and dangerous practitioners.

The present Pennsylvania bill, as stated in THE REPORTER last week, provides for a Medical Council which shall supervise the three Medical Examining Boards, and see that the three boards keep to the same standard of proficiency in their examinations.

The determination of how much the applicant for license to practice knows of general educational topics, before being allowed to appear before the examining board, and the question of the validity of his medical diploma, and of his moral fitness for the profession rests with the Medical Council. In fact the bill creates what is practically a single licensing board with three examining committees under its jurisdiction. This is a little more cumbersome than the original method, but will, it is believed, be equally good. The Legislative Committee modified the original bill of the State Society after holding a conference with the officers of the State Society and representative members of the profession connected with the

great medical schools of the state.

Pennsylvania has so long been without a proper medical law that THE REPORTER earnestly urges all to give aid in securing the passage of the present Boyer bill. Many may feel that they would like to criticise individual features of the proposed act; but it must be remembered that our first duty is to protect the public from dangerous charletans and ignorant doctors. The low grade schools graduate many such, and now Pennsylvania is one of the states in which they can with ease settle to practice. No one should oppose the proposed law except those who believe in supporting two years' medical colleges and low grade three years' schools.

Cleared Up.

It was plain from the start that the reporters would have to be called in to clear up the mystery attending Col. Shepard's death. Two physicians of the highest standing had told what they, on the spot, had made out to be the causes of death, but their official bulletin was miserably deficient in those details which the public is entitled to have in all such cases. It was only what we expected, therefore, when we found Sunday's papers, almost without exception, trying to gratify that "element in human nature," as the Boston *Herald* calls it, which insists on a daily mess of scandal and brutality. One paper, properly resenting Dr. McBurney's unwillingness to give it a spicy column, made up a "statement" of its own and put it into his mouth. Another charged him with "criminal negligence," on the strength of private information derived from a "friend of the family," and we understand that the said friend will soon be called upon to foot the bill for damages which a suit for libel will undoubtedly entail upon the paper that fondly relied upon his word. Still another reporter had a theory that Dr. McBurney was "unnerved" by a "run of bad luck" he had been having with his cases lately, and so could not be expected to act, in an emergency, with the intelligence and promptness which this reporter always has at command in his critical operations. It is highly fortunate that the physicians thus barked at are of such established character and skill. Inexperienced men in their situation would be hounded to professional ruin by the improvised doctors who would start up in every well-regulated newspaper office to show them how they had criminally blundered. As it is, we imagine that the hounding will be done by the other side.—*Nation.*

Dr. W. H. Link has observed in his capacity of Pension and Life Insurance Examiner, that hernia is the exception in *fat men.* In a communication to him, Dr. Thos. Manly of New York, confirms the observation and adds that he finds hernia in the female most frequent in fat women.

Brittle Bones.

Mrs. Peter Kelly, of Barboursville, W. Va., the woman whose bones have for some time broken like brittle glass when she moved her muscles, has died suddenly and without apparent pain. Her bones did not pain her when they broke and they knit together readily, but continued to break in new places at every muscular exertion she made.

Mrs. Kelly was in delicate health when the disease first made its appearance. She was just recovering from a long and serious illness. One evening she started downstairs to get a drink of water. When halfway down the bones of her right leg gave way with a peculiar glass-like snap without apparent cause. She called her husband, who carried her back to his bedroom. On the way the bones of her left arm broke in several places with the same peculiar snapping sound she had heard and felt when the first fracture occurred. As she was deposited on the bed the bones of her left leg broke in the same unexplainable manner, and various other bones have broken since.

The reason given by surgeons for the breaking is the deficiency of animal and a superabundance of mineral matter in the bones. The rarity and strangeness of the disease has caused it to be carefully watched by the medical and surgical fraternity. Now that Mrs. Kelly is dead the profession is desirous of holding an autopsy, but the relatives will not have it and will guard the grave.—*Roch. Herald.*

BACTERIOLOGICAL NOTES.

The Bacteria of the Stomach.

Gillespie (*The Journal of Pathology and Bacteriology* I, No. 3, 1893, p. 279) gives the results of his observations on the micro-organisms which he found in specimens of the gastric contents of patients in the Royal Infirmary of Edinburgh, suffering from various ailments. Twenty-four micro-organisms were obtained from different individuals. They were cultivated on various media to ascertain their products, especially with regard to their acid-producing power, and to estimate the effect of hydrochloric acid added to them in a similar manner to that in which it is added in life and, as far as possible, under the same conditions. The organisms obtained were largely those of well known species. The discussion of the different forms is very exhaustive with reference to the points enumerated above, but the more important conclusions deduced from the facts observed, their bearing on the etiology of dyspepsia and the treatment of that group of diseases, is all our present space will permit.

There are: "(1), Many organisms can grow in the human stomach. (2), Many of them can be grown from the contents of the stomach even when they are very acid. (3), From many cases in which organic acids are present in the stomach contents, micro-organisms can be grown which produce the same acid on suitable media. (4), Most of the organisms so grown are very resistant to the action of acids. (5), Hydrochloric acid combined with proteids—proteid-hydrochlorides—has little inhibitory power on organisms, in comparison with free hydrochloric acid. (6), More micro-organisms can be grown from the gastric contents if plates are used and a medium that will not liquefy at the body temperature, than if plates of gelatine be used. Agar-agar is a good vehicle. Yeasts and mucous, however, are best grown in bouillon, being isolated afterwards on gelatine plates. (7), Micro-organisms, if present in quantity, exercise a deleterious effect on both gastric and pancreatic digestion. (8), Pathogenic organisms, which are usually very markedly affected by hydrochloric acid, may pass through the stomach unharmed if the meal with which they are ingested be large and chiefly proteid in character. Provided also, it may be from some fortuitous circumstances, that the supply of hydrochloric acid be somewhat deficient. Under these circumstances most, if not all, the secreted acid combines with the contained proteids. (9), Many non-pathogenic germs do, as a matter of course, pass through the stomach unharmed or only temporarily inhibited. This accords with Macfadyen's observation that the bacteria of the small intestine are constantly changing in numbers and varieties. (10), A small quantity of the free acid, if combined acid be also present, is sufficient to kill or inhibit organisms which could resist a similar quantity of the free acid alone. (11), Although bacteria are of no aid to peptic digestion, and are a hinderance to the pancreatic ferment if in quantity in the duodenum, they still are of great use in the small intestine where they control putrefaction. The organisms which most easily pass the stomach are those which give rise by their growth to the fatty acids, as they are most resistant to the action of the acids. Their products in the small intestine are sufficient to keep the contents of that viscus acid, and they thereby prevent or control putrefaction. In the large intestine the secretion is so alkaline that the putrefactive organisms reassert themselves. (12), Increased putrefaction in the intestinal canal may therefore be due, in some cases, either to insufficient mortality among the putrefactive organisms in the stomach, or to too great mortality among the acid-forming bacteria and yeasts. (13), The lactic acid which appears during the first stages of digestion is due to the action of organisms. (14), The lactic, acetic, butyric, and succinic acids found in gastroectasis are due also to organisms which luxuriate in the too stationary contents.

The Parasitic Origin of Cancer.

The present theory of the nature and cause of cancer is becoming more and more questioned by the results obtained by careful pathologists, who are now advocating the theory of a parasitic protozoa as the specific cause of this form of ma-

lignant tumors. This theory is supported by Sawtscheuko of Germany, Foá of Italy, Saudakewitch of Russia, and Galloway of England, all of whom have demonstrated the presence of the parasite within the carcinomatous cells.

Ruffer (*Britist Med. Jour.*, Nov. 5, 1892) has described the intra-nuclear stage of the parasite. The protozoa first appear in the nucleus of the cancer as small, hard, deeply stained spherical bodies, hardly distinguishable from the nucleolus of the cell. They rarely occur single, but appear in groups of from two to twenty. When filled with these spores the nucleus has a dark appearance and its edges are irregular. When developed more fully, the organism becomes more transparent, and finally a minute nuclear body appears in the center of each parasite and the surrounding capsule becomes distinct. Occasionally one of the parasites increases in size at the apparent expense of the others. They gradually make their way from the nucleus of the cell into the protoplasm. They were most numerous in soft, rapidly growing cancers.

Tubercle Bacilli in the Lymphatic Glands of Non-tuberculous Persons.

Pizzini (*Zeitschrift f. klin. Med.* xxi. p. 329) gives some very interesting results from the inoculations of guinea pigs with portions of the lymphatic (bronchial mesenteric and cervical) glands from forty subjects, in which death had occurred from accident or acute disease other than tuberculosis. The animals were inoculated, under strict antiseptic precautions, either subcutaneously or in the abdominal cavity. The results obtained in thirty cases only were considered reliable. Of these forty-two per cent. were found to contain tubercle bacilli. These experiments are intended to show that under certain circumstances the tubercle bacilli after passing through the epithelum of the air passages are destroyed by the phagocytes; under other circumstances the bacilli give rise to primary tuberculosis of the lymphatics which later may become generalized, and that in some cases the bacilli remain dormant in the lymphatics, especially the bronchial gland, but retaining their virulence. The prevalence of the infection of the bronchial glands being due to the fact that tuberculous infection occurs most frequently in the air-passages, and upon their anatomical situation and physiological relation to the organ of respiration. Tubercle bacilli were not found in the mesenteric glands. In two cases they were demonstrated in the Pacchionian bodies. Too much stress is usually laid upon the mode of infection and not enough upon the resisting power of the tissues. Great importance is attached to the condition of the blood, for if this becomes deteriorated the development of the bacilli present in the glands, is enhanced.

ABSTRACTS.

PETTENKOFER'S PERSONAL EXPERIMENTS WITH THE CHOLERA GERM.*

Since the discovery of the cholera bacillus, which is a constant attendant in the fæces of all cholera patients, it is generally accepted that cholera is due to this organism alone. Pettenkofer, however, has maintained his local predisposition theory, even with regard to this disease. The etiology of cholera is regarded by him as an equation of three unknown quantities, x, y, z; x represents the cholera bacillus; y, something dependent upon locality and time (local predisposition); and z, individual predisposition. Thus, it is quite as necessary to have a predisposed locality as a predisposed individual.

Regarding the human being as the only suitable medium upon whom indisputable and incontestable experiments concerning the causation of cholera can be performed, Pettenkofer experimented upon himself. After neutralizing his gastric juice, he drank, on October 7th, a pure boullion culture of cholera bacilli which had been prepared for him from cultures sent

*Maryland Medical Journal.

from Hamburg. During the time following this he continued to partake of his usual food. His daily observations were as follows :

October 8th, one stool, normal.

October 9th, two mushy stools; two watery stools, gurgling in the intestines.

October 10th, four very watery stools, colorless, continuous gurgling.

October 11th, two very watery stools, gurgling.

October 12th, five very watery stools; temperature 36.7° C.; pulse 86.

October 13th, four, mostly watery, colored stools.

October 14th, one normal stool.

October 15th, two quite normal stools.

From this time on Pettenkofer could not perceive anything abnormal.

On October 17th, Professor Emmerich, after neutralizing his gastric juice, partook of a similar bouillon culture of comma bacilli. His observations were:

October 17th, one normal stool, two mushy and one very watery stool.

October 18th to 19th, three rice-water stools, each of 500 cc.; great thirst.

From October 19th, 6 A. M., to October 20th, evening, fifteen to twenty colorless, watery stools, each of 100 to 200 cc. In the evening of the 19th, 15 drops of tr. of opium were injected into the rectum, and following this, powders of opium and tannin were given.

From the night of October 19th to 20th he had eight, and from the 20th to 21st of October, twelve colorless, watery stools of from 100 to 200 cc.

On October 21st, the first mushy stool was noticed.

From now on the stools were more consistent, and on October 24th, the stools were consistent and well formed.

In the diarrhœic stools of both Pettenkofer and Emmerich cholera bacilli were found in abundant quantities.

From these two experiments made upon the human being, Pettenkofer draws the conclusion that the comma bacillus does not produce a specific poison in the intestine, which is the cause of cholera.

Although we must look enthusiastically upon these wonderful experiments in which Pettenkofer and his colleague offered their lives in the interest of science, we must agree with Frænkel that they prove quite the reverse of what was intended. Pettenkofer points ironically to the fact that Koch and his followers claim that he and Emmerich had really passed through an attack of cholera.

If we examine the cholera cases described by Guttman, in which the only marked symptoms were the diarrhœic stools, we must agree with Frænkel that both Pettenkofer and Emmerich suffered from slight forms of the cholera. From experiments made by Frænkel, it has been shown that cultures of cholera bacilli lose part of their virulence after a time. This, together with the fact that all persons are not equally susceptible to severe attacks of cholera, may explain why Pettenkofer and Emmerich did not suffer from a severe form of the disease.

Since Pettenkofer believes he has proved that the comma bacillus cannot be looked upon as the only cause of cholera, he tries to show what other factors are concerned in the question. He points out, in a series of extensive statistics, that time and local predisposition of the soil are the important factors in influencing an outbreak; that dryness and a low position of the soil water were present during the summer of 1892, in Hamburg; without these the comma bacillus could not have developed. It may be remarked that the same heat, dryness and low state of soil water were general throughout Germany during this period. Why did the Hamburg epidemic not become general in Germany? An important fact has been brought out by Wallichs, viz.: In certain long streets, half belonging to Hamburg and half to Altona, the epidemic was quite general on the Hamburg side, whereas but few cases occurred on the Altona side. As Wallichs points out, nothing but the difference in water supply can account for this fact. Pettenkofer speaks harshly of the many regulations taken during the past year for the prevention of the spread of the comma bacillus. Inasmuch as he admits that the comma bacillus is a factor in the causation of the disease, and inasmuch as we are somewhat helpless in the regulation of the local predisposition of the soil, we cannot see why Pettenkofer objects to measures which prevent the spread of comma bacillus. Certainly the wonderful results of the regulations, which have been general throughout Germany during the past half year, show how, by proper precautions, the spread of this dreadful disease may, at least in part, be prevented.

CURRENT LITERATURE REVIEWED.

THE MONTREAL MEDICAL JOURNAL

for March contains a paper by Dr. George E. Armstrong on

Prostatectomy

in which the author reports four cases with two deaths. He agrees with the following propositions advanced by Mr. A. F. McGill at the meeting of the British Medical Association in 1889:

1. That prostatic enlargements which give rise to urinary symptoms are intravesical and not rectal.
2. That retention is caused by a valve-like action of the intravesical prostate, the urethral orifice being closed more or less completely by the contraction of the bladder on its contents.
3. That in many cases self-catheterism is the only treatment required.
4. That when catheter treatment fails or is unavailable, more radical measures are necessary.
5. That this treatment, to be effectual, should for a time thoroughly drain the bladder and permanently remove the cause of the obstruction.
6. That these two indications are best fulfilled by a supra-pubic rather than a urethral or perineal operation.

The author finds that the supra-pubic entrance gives the operator perfect command over the seat of disease, and also sufficient drainage to the diseased bladder. Hemorrhage is troublesome, and often requires more efficient control than is given by hot water. In three cases, the author packed the bed from which the tumor was shelled out with sticky iodoform gauze. This was very satisfactory. The gauze was removed in twenty-four to forty-eight hours. The packing is in front of the orifices of the ureters and thus does not stop the flow of urine into the bladder. "The mortality attending this operation limits its peformance to the few advanced cases unrelieved by any other method. On the other hand, delay which allows the patient to drift along until general deterioration and changes in the kidneys are so far advanced as to render operative treatment hazardous, is unscientific and unsurgical." The author does not see anything in the operation itself, performed on a man whose other organs are healthy, that should make it fatal; and believes that increased knowledge of the pathology of prostatic disease and its sequellæ, with an improved technique, will enable us to afford relief to a greater number of this class of patients in future than at present.

Dr. J. G. Adami presents a report as to the microscopical appearances of three of the tumors removed by Dr. Armstrong. He regards them as a true hypertrophy of the prostatic tissue, an hypertrophy affecting all the elements of the gland. The condition may be spoken of as a partial or localized hypertrophy of the prostate.

Dr. H. S. Birkett contributes a paper on

Empyema of the Antrum of Highmore,

reporting seven cases. The causation, symptoms and differential diagnosis of the disease are discussed in a most thorough manner. The treatment advocated is as follows: "Having decided which tooth is most likely to be the cause, presuming that dental caries or alveolar periostitis has been the exciting cause, this one is to be extracted—by preference the first molar. Then the drill should be inserted into the posterior socket and made to penetrate the antrum." Should, however, there be a fistulous opening in the gum, this spot should be selected. The cavity is syringed out with an antiseptic solution—preferably bichloride, 1 to 5,000. A drainage tube is then inserted, care being taken that the tube does not extend too far within the antrum to allow the ready escape of the pus. The treatment now consists in washing out the cavity three times daily with an antiseptic solution, preferably Listerine (℥i to ℥i) as there is danger from poisoning with any stronger antiseptic. In chronic cases, where there is a pyogenic membrane, the cavity may be injected with peroxide of hydrogen every other day.

Dr. J. D. Balfour contributes a paper on the "Administration of Chloroform and the Dangers incident thereto," an abstract of which will be found in our next issue.

THE CHICAGO CLINICAL REVIEW FOR MARCH.

In an article on "Brain Surgery," Dr. F. Shaefer reports a case of injury received five years ago and which was followed three years later by convulsions and paralysis. At the operation, a blood clot was found under the dura mater and removed. The patient recovered from the operation and at the time of the communication is reported as improving.

Dr. F. E. Waxham gives his "Impressions of Albuquerque, N. M., as a health resort." As a winter residence it presents many advantages to a large class of tubercular patients and, if the disease is not too far advanced, they may expect much benefit from this extremely dry, rare climate. Feeble and emaciated patients do better in a warmer climate and a lower altitude. The summer temperature at Albuquerque is too high for most patients, though some do well by going to the mountains in the vicinity. He believes that while Colorado offers greater attractions as a summer resort, New Mexico as a winter residence is almost unequalled on account of the extreme dryness, purity and rarity of its atmosphere.

The results of the

Recent Vaginal Oophorectomies

performed by Prof. Henry T. Byford are reported by Dr. J. T. Binkley. Four cases in all are reported.

1, Prolapse of both ovaries with chronic ovaritis.

2, Ovarian abscess and pyosalpinx, left side.

3, Hydrosalpinx, inflammation, hyperplasia of right ovary.

4, Small right ovarian tumor, left ovaritis, double salpingitis, and universal adhesions.

The patients all recovered. "Dr. Byford prefers removing diseased ovaries and tubes, small ovarian tumors, through the vagina, because of the safety of the method and the absence of all trouble from hernia or abdominal fistulæ. All septic changes and retained secretions that would have resulted in general peritonitis have invariably been relieved by discharge through the vaginal incision, either spontaneously or after pushing the finger through the cicatrix, except in one case of pyosalpinx, in which the infected ligature ulcerated into the rectum."

Dr. George W. Newton reports a case of

Multiple Fracture of six bones of the Face and Destruction of the Right Eye.

The injury consisted of a double fracture of the inferior maxilla, a compound comminuted fracture of both nasal bones, a compound comminuted fracture of the superior maxilla, fracture of right malar bone and fracture of right palate bone, also total destruction of right eyeball. Hemorrhage, which was profuse, was controlled by ice and hypodermic injections of ergotine. Hot fomentations were applied for twenty-four hours, at the end of which time the patient was chloroformed and the injured eye enucleated; the fragments of inferior maxilla, wired and a fragment of superior maxilla which was hanging by only a shred of mucous membrane, dissected out. For the first three days the patient was nourished by enemata, after that he could take liquid foods. At the end of six weeks the wire was removed from the inferior maxilla, the union being firm, as it was in the rest of the bones. The face had assumed its natural appearance.

Dr. Charles Warrington Earle discusses "Retroversion and Retroflexion of the Pregnant Uterus." The treatment consists in the avoidance of any great exertion. The urine should be voided with great regularity. If spontaneous replacement does not take place, careful manual reposition must be resorted to with the patient in the knee chest position, the fingers being the best repositor. After the replacement the patient should remain in bed or should wear a pessary till it is certain that the uterus is above the promontory of the sacrum and will remain so.

Dr. Henry M. Lyman reports two cases from the Neurological Clinic of the Rush Medical College. The first is a case of "Convulsive Tic." At sixteen the patient received a scalp wound in the region of the fissure of Rolando from which he was unconscious for two weeks. Four years later the irregular muscular movements commenced. Two years ago the patient was trephined over the point of injury without relief. Dr. Lyman advised suspension of the patient by Sayre's apparatus for a slight increased length of time each day.

The second case is one of "Insular Sclerosis of the Lateral Spinal Columns," coming on after working late at night in a draught. The treatment advised was iodide of potash in small doses, rest and general care, and the galvanic current of a strength of five milliamperes for about three minutes every other day.

The other papers in this month's issue are: "Dislocation of the Crystalline Lens," by Dr. Cassius D. Wescott; "Selections from my Case Book," by Dr. E. J. Gardiner; and "Cerebral Hemorrhage," by Dr. Sanger Brown.

THE CHICAGO MEDICAL RECORDER

for March contains an article by Dr. Edwin J. Kuh.

A Topical Treatment of Bronchitis.

Direct inhalation is applied from a Davidson atomizer producing a very fine continuous spray; the patient being instructed to make as long an expiration as possible, then begin inhaling gently and slowly, and then more rapidly and deeply. The formula which has given the author the best results consists of menthol, one to two per cent.; creosote, one per cent.; camphor, one-half to one per cent.; oil of eucalyptus, two per cent.; oil of pine needles, two per cent., in albolene or benzoinol. The average quantity to be inhaled is two drachms; beyond that the patient gags and the stomach revolts. The author reports good results in old cases of chronic bronchitis, in bronchitis complicating chronic nephritis and diabetes. It is also an excellent palliative in hay fever.

Dr. F. C. Hotz presents the "Report of a case of Thiersch's Skin Grafting on the Conjunctiva." The case reported is one in which the patient lost his eye from flying glass from a broken bottle. The scar tissue, which formed after the removal of the eye, prevented his wearing an artificial one and the operation was performed to enable him to do so. The grafts were cut by passing a razor just below the cuticle, cutting through the tops of the papillæ; they are truly skin shavings, are almost as thin as mucous membrane, but being taken from a firmer texture they have a greater resistance and greater vitality than mucous membrane. The reporter has used the method with success in cases of symblepharon and in cases of large pterygium.

Dr. Christian Fenger reports a number of "Operations on the Kidney," including two nephrectomies for carcinoma with one death. Three cases of nepro-lithotomy, all of which recovered. Two cases of nephrotomy for stone in the kidney, with one death. One case of nephrectomy for traumatic rupture of the kidney; recovery. He also reports one operation for stone in the ureter, with recovery. One exploratory operation for stone in the ureter; recovery. Two cases of stricture of the ureter, one of which was traumatic; both recovered. The reporter also discusses

the operation for pyonephrosis, giving the technique.

Dr. Edmund Andrews discusses the "Management of certain cases of Recurrent Urinary Calculi without cutting or crushing," reporting a number of cases in which he succeeded in pumping the stone out of the bladder. He also describes a "New Clamp for bony union of Fractured Patella" which is a modification of the principle of the well known Malgaigne hooks. A cut of the instrument is given in the paper.

Dr. Charles Warrington Earle contributes a paper on "Mediastinal Abscess and Tubercular Bronchinal Glands," reporting cases.

The papers in this issue were read in the Chicago Medical and Chicago Pathological Societies.

PERISCOPE.

MEDICINE.

Quinine in the Treatment of Wounds.

Dr. Isidor Alfoldi (*Kozegeszegugyi Kalauz.*) recommends quinine for the treatment of wounds. The first case in which he employed it was one where in consequence of severe contusion of the foot, amputation of the leg had become necessary, and where, in spite of the most rigid antisepsis, several days after the operation the edges of the wounds and the parts surrounding them had been colored blue and showed no tendency toward healing, the flaps themselves becoming cold. This condition grew rapidly worse, and despite the usual antiseptic measures, gangrene appeared imminent. By the applidation of cotton wads saturated with a one per cent. solution of quinine sulphate, gangrene was prevented, the wound daily assumed a more healthy appearance, and healed in the normal time.

The second case was in a child of six months who had a cavernous new-growth in in the right arm, which Dr. Alfoldi treated at his clinic with Vienna caustic. A week later the wound was gangrenous in consequence of negligence, and extensive erysipelas was present. After washing the wound with a one per cent. solution of quinine sulphate and applying the dressing of gauze and cotton impregnated with the same solution, the wound became perfectly clean and presented red granulations, the erysipelas disappeared, and a rapid cure survened.

The third case was one with numerous soft chancres about the glans, which were dusted every other day with quinine sulphate. After four dressings the ulcers were healed.

The author states that infected wounds showing no tendency toward cure deterge and heal more rapidly under the influence of quinine than by the application of corrosive sublimate or of iodoform; and that simple wounds heal strikingly fast.—*Merck's Bull.*

Salicylate of Bismuth in Infantile Diarrhœs.

Mikhnevitch (*Med. Obozrenie*, No. 6, 1892), having tried the salicylate of bismuth in fifty cases of diarrhœa in infants under two years of age, reports that of the number only two died (a boy eight months with pelvic suppuration consecutive to intractable colitis, and an infant of five months, born prematurely and exceedingly sickly at its birth. The following formula is recommended:

℞ Bismuthi salicylici.....gr. xxiv.
Gummi arabici.....5 j
Sacch. albi.....5 jss.
Terendo adde aq. dest.....ʒ ij
Fiat lac, tum adde aq. dest...ʒ iv.
M. D. S.

The bottle to be kept in cold water or ice, and to be shaken well before use. One or two teaspoonfuls to be given from three to six times daily. Each teaspoonful of the mixture contains about half a grain of the salicylate, which constitutes a normal dose (three or four times daily) for an infant of from six to eight months old. In cases of offensive diarrhœa the administration should be preceded by a dose of castor oil. The bismuth salt should be given regularly until the diarrhœa has completely subsided. It must be kept in mind, however, that in large doses the remedy is apt to induce perspiration with consecutive weakness (especially in exhausted children), hence a corresponding reduction of the dose may be necessary. In acute cases the remedy is useless, but in all of a week's standing or longer its effects are said to be excellent.

SURGERY.

Bow-Legs.

Dr. A. E. Hoadley (*Chicago Clinical Review*) says:

Rugged and rapid development produce bow-legs, and more commonly straight legs, which will uniformly correct themselves without assistance.

The severe forms of ordinary bow-legs, especially where the joint itself partakes largely of the deformity, will require treatment by restraining and corrective force.

The prognosis, in the ordinary forms of bow-legs, is very favorable under the influence of mild corrective force.

The prognosis in rachitic bow-legs is unfavorable. When this condition is of long standing it is practically not amenable to treatment by gradual corrective force, and therefore should be corrected by osteotomy. The rachitis itself requires the most careful

and comprehensive constitutional treatment.

The anatomical arrangement of muscles favors the spontaneous correction of bow-legs, and the biceps is the most important in the exercise of this corrective force. In the opposite condition, or knock-knee, there are no opposing muscles that can act as correctors of the deformity.

The strong contrast between these two conditions, bow-legs with a tendency to recovery, and knock-knee with a tendency to progression and difficulty of correction, is due entirely to the anatomical arrangement of the muscles.

GYNECOLOGY.

Rapid Method of Locating Intestinal Wounds.

Dr. D. D. Crowley (*Occidental Medical Times*) says:

Large fæcal accumulations materially hinder the insufflation of hydrogen gas, usually increasing the time required to pass the ileo-cæcal valve by five to six minutes.

Fæcal accumulations also obstruct the point of the rectal tube, and may at times prevent the gas passing into the rectum.

Insufflation of hydrogen gas does not materially hinder the suturing of the abdominal wall, nor does it force the intestines from the abdomen during insufflation, as it is often stated.

The carbolized solution employed answers two purposes; by removing blood and other extraneous matters, and by acting as an element through which the escape of gas from an intestinal wound becomes visible.

The use of gas alone reduces the time required in exploring the abdomen for intestinal wounds at least 75 per cent., but with the addition of an antiseptic solution the time can be reduced 90 per cent.

With gas and fluid no difficulty is experienced in ascertaining the presence of the smallest wound in the intestine.

A wound $\frac{1}{3}$ to 1 inch or more in length, in any part of stomach, may be located by these means.

A small wound, $\frac{1}{4}$ inch in length, on the posterior surface, or a small valvular puncture in any part of the stomach, is not always readily located by the use of gas and fluid; but these two exceptions, as I have ascertained, usually do not require surgical interference.—*American Lancet.*

Ectopic Gestation.

Dr. James W. Ross, of Toronto, (*American Gynecological Journal*) writes an interesting article on the above condition. He sums up the causes of extra uterine gestation as follows:

1. Malformation of the internal genital organs.
2. Occlusion of the inner end of the Fallopian tube.
3. Pressure on the tube or obstruction of its lumen by fibroid tumors.
4. Gonorrhœal or other salpingitis.

The symptoms of disease before rupture are:

History of Labors.—In most cases there had been a considerable period of sterility preceding the ectopic gestation;

History of Tubal or Pelvic Disease.—This will usually have been present. The history often shows that the patient had a bad miscarriage some time before, or a supposed recent miscarriage.

Menstrual History.—May, perhaps, have missed a month, or a period has been anticipated, scanty or delayed a day or two. Then irregular discharges of blood have begun, and sometimes been so severe and dangerous to the patient as to require plugging. They are like the pains of a miscarriage, and sometimes these hemorrhages will come on two, three, or four times in a month. In some they will be almost continuous.

This discharge, with the passage of decidua, makes the patient assert positively that she has had a miscarriage.

Pain.—Some have no pain. Others have dysuria, or frequent desire to micturate, a desire to strain, a feeling as if something were coming down. Pains may be paroxysmal, like labor pains, or may be accompanied by a gush or a discharge of blood.

Breasts.—Some have shooting pains in the breasts with a hot feeling. Breasts may tinge and feel full. Milk may be present.

Nausea.—Evidently not a reliable symptom.

Examination.—Vagina may be of a purple color. The cervix, perhaps, is soft and patulous. Uterus may be pressed forwards or backwards, to one side or the other. An irregular swelling that feels knotty and boggy will be found in its neighborhood. Some say the tumor may pulsate. No placental souffle can be made out at this early period, even with the stethoscope in the vagina.

ARMY AND NAVY.

U. S. Army, from April 2, 1893, to April 8, 1893.

By direction of the Secretary of War Major Augustus A. De Loffre, surgeon, will be relieved from duty at Columbus Barracks, Ohio, upon receipt of this order, and will report in person to commanding officer, Fort Logan, Colorado, for duty as post surgeon at that Station.

The leave of absence granted Captain Edwin F. Gardner, Assistant Surgeon U. S. Army, for seven days, is extended twenty-three days.

Excursions to Washington.

Personally conducted tours to Washington have been arranged via Royal Blue Line, to be run at frequent intervals from New York and Philadelphia to Washington. The next excursion will be on April 6th. For programme, describing these tours, write to Thos. Cook & Son, Agents B. & O. R. R., 261 and 1225 Broadway, New York, or 332 Washington Street, Boston Mass.

SOLD BY
LEADING DRUGGISTS,

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

NO WAX

Is used in our **Hollow Suppositories.** Made from purest **Butter of Cocoa only,** which **melts** at the temperature of the **body.** Can be filled with any medicine. Anal, Nasal, Urethral, Cystic, Vaginal, and Intra-Uterine sizes.

Also, Ricord's Solid Suppositories for Gonorrhœa, and Nelaton's Solid Suppositories for Constipation and Piles. Samples sent Free on application and mention of this paper.

FEMORAL ANEURISM — TREATMENT BY COMPRESSION.

RUSHTON MOLLOY, M. D., Caledonia, Miss.

The treatment of aneurism by compression originated with Bourdelot at the close of the seventeenth century, afterwards used by Geuga, Heister and others. These surgeons made pressure directly upon the sac, and related several cures effected in this way. But this practice soon fell into disuse because of the danger and uncertainty in its results from irritating and inflaming the sac. The French surgeons modified the pressure plan by laying open the sac, clearing out its contents, and applying the pressure directly to the opening into the vessel. In 1785, John Hunter substituted for these barbarous modes of treatment, the Hunterian Operation, one of the greatest advances of modern surgery ever made by the single act of one man.

This operation was the simpler and more scientific procedure of ligating the artery at some distant and healthy portion of the body above the sac. For more than half a century this operation was almost the only method by which this disease was treated when situated upon an artery applicable to the operation. In 1810, Pellatan and Dubois applied pressure to the artery above the sac, instead of to the aneurism itself, and various attempts were made to methodically treat aneurisms in this way.

In 1841-'42, the Dublin surgeons introduced the practice of compression in the treatment of aneurism into modern surgery, and demonstrated by pathological investigation and surgical argument that the coagulation of the blood by which an aneurismal sac is occluded, may take place as readily when the current of blood from the artery into the sac is interrupted by compression as when it is arrested by ligation of the vessel. They established this great fact, that whenever the artery could be reached so as to admit of compression between the sac and heart, the tying of the vessel was no longer the only hope of cure in this formidable disease. When the practice was first used by the profession, the theory was erroneous; it was supposed that the whole flow of blood through the artery should be arrested and inflammation of the vessel at the point compressed should be secured and that the consolidation of the aneurism depended upon the obstruction of the vessel subsequent to this inflammation. This led to the employment of too violent and forcible compression, causing the patient great pain and often sloughing of the skin.

It is not necessary that the whole of the circulation through the artery be entirely and permanently arrested, but merely be lessened in force and quantity to such extent as is compatible with the deposition of laminated fibrin. Erichsen reports a case of popliteal aneurism operated upon by Sir Charles Bell, in which the femoral artery was double, only one branch being secured the other continuing to supply the tumor; on examination a week later, the patient having died from erysipelas, the tumor was completely consolidated. In some cases consolidation of the contents of

the sac takes place in a few hours, not by the deposition of fibrin but by the coagulation of the contents of the sac. This sudden coagulation, which was at one time dreaded by surgeons, is now considered to be in the highest degree advantageous, as leading to a more rapid and equally sure cure of the aneurism; but is not to be desired in aneurisms situated upon arteries supplying the brain because of the great danger of syncope, or hemiplegia in consequence of a detached portion of this soft clot forming an embolus in one of the cerebral arteries.

Usually the interior of an aneurismal sac contains a quantity of colorless fibrin, arranged in concentric laminæ of moderate thickness. These laminæ of fibrin are of a pale-buff color. The more external were deposited first and occasionally are found to have undergone a kind of fatty degeneration. As the center of the sac is approached they become softer and more colored and in the central portions dark masses of coagulum are often met with. This laminated fibrin, the active clot as termed by Broca, is deposited only when the blood is in motion in the sac of the aneurism, and is usually if not always found in aneurisms of the saculated variety, because the movement of the blood is necessarily much slower in this variety than in the fusiform, in which the flow of blood is rapid and adhesion of the corpuscles take place with difficulty. The color of the clot varies in different cases; the more rapid the flow the fewer red corpuscles will be found in the coagulum, the slower the flow the darker the clot will be. Complete arrest of the circulation leads to the formation of an ordinary dark clot exactly similar to one formed outside of the body.

This laminated fibrin, which we should always hope to have deposited, is formed in the same way as a colorless thrombus in a diseased vein; the first step in the process being the adhesion of the white corpuslces to the walls of the sac; by the disintegration of these white corpuscles the fibrin ferment is produced which acts upon fibrinogen and fibrinoplastin to form the fibrin in the delicate meshes of which all the elements of the blood are collected, thus forming the clot.

Of the great value of compression in the treatment of aneurism, there can be no doubt, especially when the tumor is situated in the arteries of the lower extremity. Aneurisms occurring in the vicinity of the trunk are not so applicable to the treatment by compression as those of the extremities, although an aneurism in the groin has been cured by compression of the abdominal aorta. The great value of compression is that if it fail the ligature may be advantageously applied, with in some cases, a better prospect of success than if compression had not previously been tried, the pressure causing the collateral circulation to enlarge, thus lessening the tendency to gangrene. But in a great many cases the difficulties of the operation of ligation are greatly increased by the thickening and infiltration of the sheath of the vessel subsequent to the treatment by compression. Compression may be safely employed in some cases, as when aneurism is complicated with a heart trouble in which the operation of ligation is not advisable. In some few cases neither ligature nor compression can be adopted and amputation is the sole reliance, while in other cases compression, especially in femoral and popliteal aneurisms, is an infinitely safer method of cure.

The duration of the treatment by compression varies very greatly. In some cases the tumor solidifies in a few hours. In other instances the compression has been used for more than three months before a cure resulted. For instrumental compression, according to some statistics, the longest period was seven weeks. The shortest twenty-four hours; the mean of nineteen cases, in which time was recorded, was twelve days.

For digital compression, the longest period was twenty-one days, the shortest four and one-half hours, the mean of thirteen cases five and one-half days. For combined instrumental and digital compression the longest period was six months, the shortest forty-four hours, the mean of twelve cases forty-four and one-third days.

In regard to the duration of treatment much will depend upon the condition of the patient and on the condition of the tumor. Those circumstances favoring the spontaneous cure of the aneurism will also influence the rapidity of the cure by compression. There are certain conditions of the blood in which it is little disposed to coagulate; in such cases the treatment will necessarily be prolonged.

Any constitutional cause or condition by which the impulse of the heart is lessened and the force of the flow of blood through the sac is diminished, as the occurrence of phthisis, will greatly favor the deposition of laminated fibrin and the consolidation of the tumor. It is very remarkable that phthisis is antagonistic to aneurism and may be explained by the fact that the heart's action is feeble in that disease, and that violent muscular exercise is rarely undertaken by those afflicted with it. The effects upon the tumor treated by compression vary considerably, in some cases it rapidly solidifies; generally, however, this is a more gradual process, the tumor becomes more painful and solid with less pulsation and bruit, and usually there is a feeling of restlessness and uneasiness which is best to quiet by opiates. As the pressure continues the tumor hardens, the anastomozing vessels enlarge, with a feeling of burning pain in the limb and arterial pulsations where usually none are felt. After complete solidification of the aneurism has taken place, the pressure should be continued for forty-eight hours to prevent the occurrence of a relapse.

Report of case: Nathan W., colored, age forty-three years; weight near 200 pounds; about six feet high; a planter by occupation; noticed in January, 1891, a small tumor in left groin about the size of an almond. It gave him but little trouble however, and he continued at his work until February of the following year, (1892) when he began sowing and plowing in oats. I might say that the negroes of the South do but little work during the summer and autumn months, except to gather their crops —which is easy work. This long period of idleness, perhaps, explains the slow growth of this tumor. In February, when he began to plant and prepare his land for cultivation, his left leg became so stiff that he could not climb over a fence and was obliged to quit work and to use a cane in walking. About this time he sought the advice of my father, complaining mostly of stiffness of the limb and inability to perform his duty as a farm laborer. My father examined the tumor and felt plainly the pulsations and heard the bruit. Believing that he had in former years cured a popliteal aneurism by the use of ergot he prescribed it in this case, giving fifteen drops every four or five hours, during the day of the f. e. ergot. After using this remedy for a short while the stiffness of the limb seemed to abate and he was able to walk without the assistance of his cane. In April, owing to a very rapid rise of the river and the overflowing of its banks, he was compelled to make some gigantic efforts, which taxed his strength and endurance to the utmost, to save himself and family from the flood which covered the bottom lands; during this time he was for several hours swimming and wading about in the water and for two days or more he was in a house which was surrounded by water, being much exposed all the while.

After this the tumor began to rapidly enlarge and to pain him a great deal. About this time, May 1st, I was called to see him—my first visit. I found him suffering great pain, his body being convulsed with it, and wet with perspiration. I immediately used morphia and atropia, putting it under the skin, with the success of relieving the pain in a few minutes. I also left morphia to be taken should he have another paroxysm of pain, and continued the use of the ergot. At my next visit, a few days later, I found him in almost the same condition as I did at first, except the pain seemed more like sciatic neuralgia than before. I again used morphia and atropia with the same result as before, and decided to discontinue the use of the ergot and to use the iodide of potassium instead, giving ten-grain doses three times a day. The patient had inherited a scrofulous diathesis from which he had suffered when young. On the sixth of May Dr. J. D. Egger was called in consulation with my father and myself. At this time I was very much in favor of an operation and urged the patient to consent, as I had been doing previously, but he persistently refused. The tumor now occupied the whole of Scarpa's triangle, running up so close to Poupart's ligament that I did not think pressure could be used. The paroxysms of pain seemed to recur regularly, simulating a malarial affection, but quinine did not prevent their return or make them any lighter. The iodide was continued with morphia to relieve pain. At our next consultation, about the middle of May, Dr. Egger proposed to use pressure, and by his ingenuity and workmanship

an instrument was made of a steel spring, shaped like a horse shoe with a wooden block on one end through which worked a thumb-screw with a cork on the end, the cork to direct pressure upon the artery as it crossed the pubes, the only place possible for pressure to be applied. This rude instrument was applied the latter week of May, and seemed to prevent the main inflex of blood. The patient was shown how to manipulate the instrument and directed to keep it on during the day only. The iodide had now produced its physiological effect and was discontinued as he refused to take it longer.

The paroxysms of pain continued to recur during all this time; sometimes two or three paroxysms a day, then other days he was entirely free of them.

After using the instrument about eighteen days he left it off, declaring that he could not use it any longer as it caused him too much pain by irritating the skin. He now consented to an operation and Drs. J. D. Egger and W. S. Green were called, but the aneurism had extended so far as to involve the external iliac, and a successful operation was thought to be impossible. He was again put upon the iodide of potassium with the syrup of the iodide of iron. His leg began to swell and become very œdematous; pitting on pressure to the toes; the superficial veins became enlarged, resembling whip cords, showing plainly the effect of the pressure upon the returning circulation. He was rapidly becoming addicted to the use of morphia, not less than three or four grains giving him any relief. He was unable to turn himself in bed, and complained of dull, aching, throbbing, burning pains. His appetite was poor, and he developed a cough with expectoration simulating phthisis; was greatly emaciated, his leg being as large or larger than his body. I directed him to use cod liver oil, to be alternated with Fellow's syrup of hypophosphites, and to rub his leg several times a day always in the direction of the heart. In this way his cough diminished, appetite returned, the pains in his leg ceased, the morphia was left off entirely and he seemed to be better in every respect. His leg gradually returned to its normal size, the tumor became very hard and diminished in size, the bruit and pulsation ceased entirely, and now he is walking about his farm on crutches, though perfectly able to walk without them. The only impediment to free locomotion is an inability to perform freely the movements of extension and adduction.

CLINICAL LECTURES.

NOTES ON A CASE OF EXTRA-UTERINE PREGNANCY IN THE PRACTICE OF DR. MORDECAI PRICE.

W. H. LINK, M. D., Petersburgh, Ind.

Mrs. J. C., February 6th, missed a period. February 18th, had a severe fall followed by hemorrhage from the uterus, with shreds of membrane discharged. This continued up to the day of operation. Twenty-six days after the fall and the appearance of hemorrhage, she was seized with most agonizing pain in the pelvis attended by a constant desire to stool without the ability to do so. Coincidently there was a marked tendency to faint, while the most startling pallor called attention to her facial expression.

Notwithstanding these emphatic and clearly marked symptoms of tubal pregnancy with rupture, which ought to have been understood and appreciated by any professional man of ordinary intelligence, her medical attendant failed to realize her condition. What his diagnosis was could not be fathomed by the treatment instituted. He curetted the uterus, packed the vagina and sent for a large Hodge pessary which he introduced and left *in situ*. This treatment gave such agonizing pain and increased her apparent illness so much, that her doctor was discharged and another called in. He promptly removed the pessary and stated that he did not understand the case. Dr. Price was

then called to see her and found, upon examination, more positive indications of ruptured tubal pregnancy than are usually known to manifest themselves in such a catastrophe.

Physical examination showed a large boggy mass to the left, extending as high as to the crest of the ilium. The uterus pushed high up under the pubis. Douglas' pouch filled with a fluid, fluctuating boggy mass, and the patient was exceedingly feeble with a pulse of a hundred and thirty.

Section was at once suggested by Dr. Price as the only means of saving life.

On the morning of April 4th, the abdomen was opened by a small incision and a quart of clots turned out of the pelvic cavity. The left tube was quickly brought up and tied off. The rupture had occurred at the fimbriated extremity and the placenta was still within the tube which was distended to the size of a small lemon. On the right side there was a large collection of pus in the tube, which was ruptured in the process of enucleation, flooding the pelvis with pus. There were strong, dense, and multiple adhesions to the bowel and ovary. These adhesions were so numerous and so firm that complete obstruction of the bowels had taken place, and the resulting distension added much to the difficulty of the operation. In breaking up the firm adhesions between the bowel and pus sac the peritoneal covering was torn on three kunckles of intestine. These were repaired with carefully placed Lambert sutures. The bowel was replaced after repeated douching, the abdomen thoroughly flushed, a glass drain inserted, the incision closed with silkworm-gut, a six-tailed bandage applied and the patient put to bed. She rallied promptly and has continued to improve up to date.

There are a number of deductions to be drawn from this case that are worthy of careful consideration.

The array of important symptoms:

She had missed a period. This is a classical symptom that has few exceptions. Pregnancy without the uterus inhibiting menstruation as certainly as if within that viscus, and often leading the patient to the conclusion that she is normally pregnant.

The early period at which rupture occurred. Rupture usually takes place before the twelfth week, but if much earlier than that, is superinduced by some traumatism, over exertion or emotional disturbance. In her case, rupture was precipitated by the fall.

The hemorrhage from the uterus was characteristic of most of such cases. In some cases of ectopic gestation so much blood is lost *per vaginam* that the mistake is made of considering the case one of uterine abortion.

The shreds of membrane passed with the blood are always sufficient to make the wary practitioner alert in looking for other symptoms.

Ectopic pregnancy is attended by a decidua just as certainly as though nature had been stimulated by the presence of the ovum in its normal receptacle. At the time of either rupture or tubal abortion this decidua is cast off and expelled as shreds or membrane, and attended usually with uterine hemorrhage as in abortion following normal pregnancy.

The agonizing pain which at once made itself felt upon rupture, is one of the most certain symptoms found in accidents of this kind. It is caused by the flow of blood and the expulsion of clots and the fœtus or its envelopes into the peritoneal cavity. A circumscribed peritonitis is at once ushered in and nature begins the attempt to fence in the dangerous material.

The constant rectal tenesmus was another finger-board pointing in the same general direction of ruptured ectopic pregnancy. The large accumulation of blood and clots pressed upon the rectal nerves and produced the desire to stool, while the mechanical pressure of the blood upon the rectum produced obstruction of the bowel and prevented any relief from the distressing symptoms.

The tendency to faint, which would no doubt soon have become a real syncope, was due to loss of blood and shock. This is one of the most unmistakable symptoms in such conditions, and is often the first alarming occurrence that leads to a physician being called.

The pallor is characteristic and is due to the loss of blood. It is in degree proportioned to the extent of hemorrhage, and must be considered with the *group* of symptoms both as to diagnosis and prognosis.

The quick, weak, almost thready pulse is a symptom confirmatory of the remain-

der of the group, and is the best indication as to the immediate danger to life of any.

The tinkering treatment she underwent before she fell into the hands of a surgeon, is a fair sample of what ignorance can do when the ass puts on the lion's skin even for a moment. Any man who would curette a uterus with so large a collection of pus as there was on one side of the patient's pelvis, to say nothing of the perfect picture presented by the group of symptoms, must either be very ignorant or very much in need of a conscience. That such ignorance could be found in a great medical center like Philadelphia is quite surprising to an observer, and speaks louder than any words for the passage of some sort of medical legislation that will at least lessen the number of incompetents turned loose upon a suffering public.

COMMUNICATIONS.

TWO CASES OF MALIGNANT DIPHTHERIA.

FRANK P. BUTLER, M. D., Marshalltown, Ia.

In presenting the following cases, I do so because of their peculiarities and complications, because they are somewhat out of the usual line, and because we were so baffled in our efforts to either diagnose or treat them successfully.

Saturday, April 23rd, 1892, Mrs. B. consulted Dr. Hedges in regard to her son, æt. two and a half years. Dr. Hedges found him suffering from a slight indigestion and prescribed accordingly. Sunday, 24th, the boy was suddenly seized with severe convulsions. Dr. Hedges being out of town, another physician was summoned. He found the child unconscious, but after a few moment's work had him sleeping comfortably. The glands of the throat were enlarged, the temperature was evidently rising rapidly, but owing to the child's condition the doctor did not deem it advisable to disturb him with the thermometer, so the exact temperature was not known. At eight p. m. of the same day Dr. Hedges was summoned. He found the glands very much enlarged; temperature 104° F; the lungs in a state of engorgement, showing plainly that he had to deal with acute double pneumonitis; the head was very hot and the face flushed.

Monday, 25th, the glands still enlarged, the lungs evidently crepitant though they were passing into the stage of red hepatization.

Tuesday, 26th, hepatization nearly complete; the breath was very fetid, gangrenous in odor, so much so that the nurse in bending over him to attend to his wants, covered her mouth and nose with her handkerchief. The hepatization became complete at seven o'clock Wednesday morning, when he died.

At 10.30 on the morning of the 27th, (the morning the boy died) I was hastily summoned to see his sister, aged four years. I found her intensely nervous, bordering on convulsions; the throat was very much swollen both inside and out; the inside red and tumified. I looked for a membrane but failed to discover one; temperature 103° F. in axilla only one hour after she was taken sick.

As her case was so much like her brother's (of which we were very much in doubt as to our diagnosis), I proposed a post mortem upon the latter, and at three p. m., eight hours after death, assisted by Drs. Lewis and Hedges, I first made an incision into the trachea, but found nothing abnormal in its entire length. Both lungs were in a state of complete hepatization and upon cutting the surface, there was seen to escape a viscid, turbid, reddish fluid, the substance of the lungs breaking down readily under the pressure of the fingers. Upon opening the pericardium we found a large effusion, probably one pint. A thorough examination of the heart revealed nothing abnormal. The liver was much enlarged from congestion.

In the jejunum and ileum were found five intussusceptions, incomplete and with no inflammatory products. The bowels moved regularly during his sickness.

Peyer's patches were found enlarged and congested, but our efforts to find an ulcer were in vain.

To say that we were disappointed with the result of our examination but mildly expresses it. We all anticipated more evidences of diphtheria, for owing to the child's anæmic appearance, the peculiar gangrenous breath, the sudden illness of the sister in the same manner, the evidences of septic influence in both, we certainly expected to find a membrane, pus or something besides the pneumonia that would account for the above conditions. Of course the pneumonia was in itself sufficient to cause death, but whence the other symptoms?

After the examination of the boy we naturally directed our attention and efforts more especially to the little girl's lungs, and by Saturday the congestion had passed off in resolution. She was bright and cheerful all day Saturday, and we considered her convalescent up to five o'clock p. m. Then she again became restless, the glands again enlarging, but there was no membrane visible, the breath assumed the same odor as the boy's, though not so intense. Sunday she grew constantly worse and, late in the afternoon, there appeared upon the left fauces a patch of diphtheritic membrane about the size of a quarter of a dollar. She gradually failed and died at twelve o'clock Sunday night.

We carefully examined the premises. The cellar was in good condition, dry and clean. The well, about twenty feet from the house, was forty-five feet deep and contained forty feet of water. It had been cleaned out about a year ago. The privy vault is about one hundred feet from the well, and is in poor condition, open and very shallow, the ground sloping from the well to the vault. They have a pet house dog that is healthy. No cats. Had seen but one rat about the house, and that only a few days prior to the children's sickness. The father had some hundred or more chickens, all healthy. They keep their own cow, she is fat and healthy.

The treatment consisted of acetanilid; quinine; digitalis in large doses; listerine, locally and internally; peroxide of hydrogen by atomizer; calomel; iron; and poultices of flax seed meal applied to the chest and throat. The parents have a babe three months old, who up to the present time remains perfectly healthy.

THE TREATMENT OF HEMORRHOIDS.

JAS. E. PRYOR, M. D., Logansport, Ind.

There is no class of diseases more important, falling into the hands of the general practitioner, and for which he should be better prepared to treat than diseases of the rectum.

Within the past few years much practical attention has been devoted to the subject and much has been said and written on this annoying branch of surgical disease.

The frequency with which we are called upon to relieve those suffering from this troublesome affection, behooves us to well acquaint ourselves with the different modes of affording relief. Many of these patients have tried all sorts of "salves" and "pile remedies." The word *operation* is a "bug-bear" to them; they are timid and discouraged, anxious for relief, and finally fall into the hands of the general practitioner, and he who can cure them, not only relieves a troublesome disease, but adds laurels to his fame.

Without going into the pathology, or any lengthy discussion as to the different varieties of hemorrhoids, or the methods of treatment, I shall merely give an outline of the results of my own thought and experience with a method which I have used successfully during the past three years.

Much has been said and written for and against using injections of carbolic acid in hemorrhoids, but I believe by using proper judgment and care almost any hemorrhoid that is a distinct internal growth can be successfully met by injection, and with a minimum of danger. But I would especially caution against using injections of too great strength, or mak-

ing too many injections at one time. It is better that we do too little than too much. A little extra zealousness or misapplied judgment will cause the patient more inconvenience than his ailment.

When a patient comes for relief from this affection, I do not accept his own statements, but make a thorough examination, both digital and ocular, before making a diagnosis. Having found out the size and extent of the trouble I prepare for treatment. I direct him to go home, have the bowels moved freely, and order a large enema of soap-suds and water to be taken just before coming to my office.

Having placed my patient in proper position, I ask him to strain so as to bring the tumors down in view, then with a clean hypodermic syringe I inject one drop or minim of pure carbolic acid in the center of each pile and then replace it. If the patient is in good condition, I do not hesitate to inject two or three at one time, but generally, it is better for him to present himself at proper intervals until all are injected. After injection I have him put to bed for a week. If there is much pain, it is controlled by an anodyne suppository, or small doses of morphine. After two or three days the bowels are opened freely.

The tumors will atrophy or shrivel up. Only in rare and aggravated cases will a tumor require a second injection; usually the pain is of little account, and in course of three weeks the patient will go about as usual.

With proper judgment and care there are but few cases that cannot be entirely cured by this treatment. I have never had any dangerous complication whatever, occur since I began using it.

SOCIETY REPORTS.

THE CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting of March 21st, 1893.

RUPTURE OF PELVIC ABSCESS; SUDDEN DEATH.

Dr. W. H. H. Wathen: On last Tuesday afternoon, I was called in consultation to see a woman, forty-five years of age, a widow, with several grown children, who was suffering with some distension of the abdomen; with pulse 80; temperature normal. Her temperature the day preceding was 102 F.; pulse a little accelerated. The history of the case, as far as I could get it from her physician, was about as follows: The patient had suffered occasionally with pain in the abdomen, not well located, perhaps a year before. She was comparatively well after that until a week before I saw her; then, at the menstrual period, she exposed herself during cold weather, and began to suffer severe pain in the abdomen, mostly in the appendicular region, and diarrhœa began which continued two days. An opiate was given to stop it; then her abdomen began distending and became tympanitic in every part; least tympanites just above the symphysis pubis and on the right side in the region of the appendix, with no special tenderness except in this region. Her bowels ceased to move, I think, about the time I saw her, and she passed very little gas after that; temperature and pulse remaining normal. No vomiting, except of substances which she took into the stomach; no odor from the vomited material and very little discoloration of it. She was a large woman, was unable to get out of bed, and was rather indifferent to everything that surrounded her. An examination *per vaginam*, showed that the uterus and all pelvic structures were matted together, the hardness being more pronounced on the right side. No accurate diagnosis could be made, but the symptoms indicated appendicitis more than anything else. It was decided to operate on her on Friday morning at nine o'clock. Thusday evening at ten o'clock her pulse and temperature were still normal. She said she was feeling better. Friday morning at six o'clock she vomited a little water that was taken during the night;

she fell over as though strangling, and in fifteen minutes was dead. After death she passed a small quantity of fecal matter, having passed no gas for several days preceding this. At the request of the family, a *post mortem* was made on Friday at two o'clock, by Dr. Louis Frank—Dr. Wilson, Dr. Pfeifer and myself being present. I will ask Dr. Frank to exhibit the specimens removed.

DISCUSSION.

Dr. Louis Frank: On Friday we held the *post mortem* as Dr. Wathen states, and when we first opened the abdomen a clear fluid came out. The thorax was not opened as is usually done. In separating the intestines and reaching the large bowel, we found that there were collections of pus which seemed to be saculated by adhesions having formed between the contents of the pelvic cavity and the posterior abdominal walls. We found a rather dark formation in the region of the appendix, looking very much like the appendix; however, it proved not to be such, and searching further we found the appendix which was in a perfectly normal condition; consequently we proceeded to examine further for the cause of the trouble. I present here the appendix which has been opened; it shows no evidence of disease or thickening. After having gotten out all of the intestines and finding nothing to account for the trouble, we proceeded to look into the pelvic cavity and found the uterus in a normal position, as were also the left tube and ovary, but in the region where we should have found the right tube we discovered an abscess sac into which the tube had ruptured. The ovary on this side was found to be cystic. The abscess had ruptured into the pelvic cavity, otherwise there was nothing of particular interest to report. I think it is rather an interesting case, and shows how liable we are to make a mistake in diagnosis from abdominal symptoms; how easily we might diagnosticate appendicitis from the symptoms, when the true nature of the trouble might be pyosalpinx or other pelvic troubles.

Dr. W. H. Wathen: This *post mortem* makes the case a very interesting one; from our general knowledge of symptoms caused by peritonitis and the accumulation of large quantities of pus, we can hardly understand how such destructive conditions could go on without causing more disturbance, especially of the pulse. Because the pulse, we are taught in our text books, is rapid and wiry in peritonitis, and we come to the conclusion, if we have a pulse relatively normal in its frequency and its volume, that we have not much peritonitis. But it teaches the lesson that we cannot rely upon the symptoms in peritonitis, either local or general, to indicate exactly or even approximately the condition of the peritoneal cavity.

You will find one abdomen distended very largely and you will operate, believing that you will come in contact with large quantities of pus in the peritoneal cavity, diffuse or localized; when the abdomen is opened there will be no pus anywhere, and you will find a little band of peritoneal adhesion constricting the bowel at one point, which is removed and the patient recovers. In another case, where the indications of pus and of peritoneal infection are not so well marked, we find either diffuse peritonitis with the cavity filled with pus, or sacculated accumulations of pus. Another thing that this case teaches is the conservatism of the peritoneal cavity in its effort to resist general infection by pathogenous germs. When this pus tube ruptured, instead of causing, as we would naturally suspect from a large accumulation of virulent pus, general peritonitis, nature hurriedly threw out a protective wall against general infection, and even after this accumulation of pus, as much as a quart or half gallon, it was cut off from the general peritoneal cavity. The peritoneal structures which were not involved in the pus sac were perfectly free from infection. Another thing it teaches is, as Dr. Frank has mentioned, our inability to diagnosticate with any degree of positiveness the origin of these intra-abdominal inflammations, because the symptoms are frequently in one locality, when, possibly, the origin of the trouble is in some other locality. In this case all the well-marked symptoms of pain and tenderness in examining the abdomen were in the appendicular region, and the trouble was found to be of tubular origin. The only evidence that it originated in the tubes was found in examining *per vaginam*; these structures were found to be matted together; but they might have been matted together in appendicitis, because leakage of pus from the appendix could produce peritonitis of the pelvic

structures. Just as in a case that I reported to this Society at its last meeting —all the symptoms complained of by the patient indicated appendicitis, but the *post mortem* proved that the trouble was entirely due to rupture of the gall bladder filled with gall stones. Just as in a case reported some time since by Dr. Dugan, where all the symptoms pointed toward appendicitis, yet when the abdomen was opened it was found the gall bladder had ruptured. So it is utterly impossible to make a positively correct diagnosis in conditions of the abdomen of this character, from the objective and subjective history of the case. Another thing it teaches is that cases of tubular trouble ought to be very carefully looked into, and where a woman suffers from conditions which point to anything of this kind, she should be carefully watched, and operated upon in time to prevent a fatal termination. I believe this woman's life could have been saved had an operation been performed two weeks before she died.

Dr. J. G. Cecil: One of the most interesting points to me in connection with this case, is the method of death, as to what really did cause the death of this patient. I would have expected in a case like this, after there had been rupture of an abscess sac, general diffusion of pus throughout the whole abdominal cavity, then a rapid infection of the general peritoneum and death in a few hours, say twenty-four or forty-eight hours. This would have been a perfectly reasonable explanation. But how a woman could die in such a condition as this, without evidence of general infection and in such a short time, is to me entirely inexplicable. I could not suggest the possible method of death in this case. She could not have died of hemorrhage, as there was no blood found; she could not have died of septic poison, as there was no evidence of that; it was not, apparently, death from shock, although that seems to me nearer the correct solution than anything else, because, as I understand, in the *post mortem* no pus was found in the general cavity at all; that as the cavity was opened there existed a small amount of clear serous fluid, which did not show any evidence of general peritonitis. It is a case which teaches a good many lessons. I think probably the cause of death might have been explained if the gentleman had carried the *post mortem* further and opened the cavity of the thorax. I am sorry that the thoracic cavity was not opened and carefully examined.

Dr. J. W. Irwin: It seems to me to be a very unique case for a person to die without any evidence that would point to the cause. It is quite possible, as Dr. Cecil has said, that if the *post mortem* had been extended higher up, the cause might have been explained. I think that the only conclusion that we can come to is that the patient died of shock.

Dr. J. B. Marvin: In perforation from any cause in any cavity of the body, do you not generally have sudden death? Where there is rupture of the gall bladder, of the appendix, gut or tube; or, if you go into the other cavity, rupture into the bronchus or thoracic cavity, of an abscess, do you not, as a rule, have sudden death? How else can you explain these sudden deaths except by shock? The termination is too sudden to be from inflammatory or septic trouble. I think in the case reported there must have been some chronic peritonitis, or serous fluid would not have been found in the cavity, and there would not have been any distension.

Dr. Louis Frank: No fluid was found until we got below the umbilicus. Fluid found in the lower pelvic cavity was pure pus. The adhesions in the upper part of the cavity were evidently of recent formation, as they were very easily separated, but in the lower part of the cavity they were very extensive and tough, and very hard to separate. I believe that there was some peritonitis, probably from contiguity of structure, and that the rupture of the tube took place twelve to twenty-four hours before death.

Dr. J. G. Cecil: In answer to Dr. Marvin's inquiry: It seems to me it is not always the history, that death takes place suddenly where there is rupture into any of the cavities. I have never seen many deaths from rupture of any kind. I remember to have seen a death from perforation in typhoid fever, which I think occurred in thirty-six hours after rupture, but was preceded by evidences of acute peritonitis, was explained in that way, with pains referred in the ordinary classic directions. Deaths from rupture of the tubes in extra-uterine pregnancy or rupture of pus tubes into

the abdominal cavity, in forty-eight or thirty-six hours are perhaps not unusual, but I take it that a death in fifteen minutes from rupture into any cavity would be very unusual; deaths from gun-shot wounds into the cavity, which would be equivalent to rupture, seldom occur suddenly, unless it be from hemorrhage.

Dr. J. B. Marvin: There must have been some change going on, or it is possible the pus sac would not have dilated. There was inflammation going on without many active symptoms, at the same time there was some lowering of vitality.

Dr. Orendorf: I think death might be explained by the fact that the sudden collapse of the abscess wall in rupture caused the heart to lose its peripheral resistance, and the shock so produced was sufficient to cause death.

Dr. W. H. Wathen: I have really very little to add, more than to say that while there was no general peritonitis, and but little accumulation of pus in the free abdominal cavity, still I was inclined to the opinion at the *post mortem*, that there had been a rupture of the great abscess cavity and I believed that death occurred just after this rupture; and there would not necessarily be any great quantity of pus in the peritoneal cavity. With the structures matted together entirely across above the symphysis pubis it was almost impossible to tell exactly where the opening occurred, because in cutting down, adhesions had to be separated after a fashion that would prevent finding the opening. I am satisfied that there was more pus in the peritoneum than was noted, and in a condition of this character, with weak resisting or inhibitory powers, I think a rupture of this nature might cause death within a very short time by sudden shock.

Dr. Louis Frank: I am inclined to think she might have died of shock; this is probably the correct solution.

Dr. J. B. Marvin: In these cases where pus forms, making an abscess sac anywhere in either of the cavities, when it does, eventually, rupture, you are very liable to have sudden death. I do not think these cases should be compared with stab or shot wounds, as stated by Dr. Cecil; where the formation of an abscess has been going on for quite a while, there is a certain amount of toxic infection lowering the resistance and vitality of the patient, and, under these circumstances, rupture into the cavity is very liable to cause sudden death.

Dr. J. G. Cecil: I did not mean to convey the idea that death from rupture of an abscess cavity into the general peritoneal cavity was to be compared in all respects to trauma, that is, an acute condition like gun shot or stab wound, but more particularly to cases of the character I cited—rupture or perforation of typhoid fever, also perforations or ruptures of pus tubes, which are not so infrequent. We very seldom hear the history of cases such as has been given to-night in rupture of pus tubes. It seems to me that the only rational explanation is that the patient referred to by Dr. Wathen, died from shock. The emptying of a large quantity of pus into the general peritoneal cavity might and probably would produce great shock, and in some instances might cause immediate death, but the general observation of cases of this kind is not that of immediate deathfollowing rupture.

For instance take cases of appendicitis—we had report of a case of death on the table or shortly afterward, in one of the other medical societies last week, in which, when the cavity was opened it was found to be filled with pus, and the appendix was found ruptured, etc., a condition not dissimilar to the case under discussion. The patient was a chronic alcoholic subject, a man who had been drinking beer and other liquors all his life, and a man who had poor resisting powers. In that case, however, death followed many hours after perforation. That was the idea I had in regard to these cases; that I could not see why rupture of the tube in the case reported to-night, should have caused immediate death, and especially since there is no history of pus in the general peritoneal cavity. A little pus in the cavity might be granted, and yet there was not, according to the report of the autopsy, very much if any, pus found in the general peritoneum. Infection of the abdominal cavity could not have taken place in fifteen minutes, so it is probable, as already stated, that rupture of the tube took place some time before, and the pelvic peritoneum provided against this general infection by shutting it off, a wall or curtain being formed around the great abscess sac in the pelvic cavity, protecting the general peritoneum.

PELVIC CELLULITIS.

Dr. J. W. Irwin: The discussion of this case alarms me, and it occurs to my mind just now that I must be making a great mistake, or I may be eventually going to kill a young lady—I say kill because if I am neglecting a case I would be responsible for her death. About four weeks ago I was called to attend a young lady, seventeen years of age, who had just menstruated. Menstruation had been normal, but afterward she was taken with violent pains about the womb, extending clear across the pelvis and about half way up to the umbilicus, and there was a considerable feeling of weight in the thighs extending down the inner sides to the knees. The patient was not nervous, and a history of nervous disease in the family was wanting. There was a hectic flush on her cheeks and considerable fever; temperature in the morning about 100° F., going up in the evening to 103° F. This condition of things had existed for five or six days. There was no discharge from the vagina, and no evidence that suppression of the menstrual function had occurred prematurely, the history being that she had menstruated for five or six days. Under the old regime we called those cases, so far as I can make out, "pelvic cellulitis." The question arose in my mind as to whether I should call in an abdominal surgeon, have the abdomen opened and the modern treatment applied, or institute the old proceedings of expectancy, so to speak, for the relief of this condition. The patient is now very much better, yet there is a good deal of soreness and stiffness in the lower part of the abdomen, and tenderness under pressure. There is no history of a gonorrhœal nature that I can discover without making an examination *per vaginam*, which I have not done, as the virginity of the patient is beyond question; consequently infection of this character is not to be considered. Her general condition seems to be improved, though tenderness still exists. She turns on the bed very badly, and when she does she has some pain, but when she remains quiet there is not much pain. There is no evidence of pus formation that I have been able to discover, and if there is pus in the abdomen, I have no idea how it could have gotten there. I believe the case will go on now to recovery as far as recovery can be had in a case of this kind. But I am at a loss to know what brought about this trouble, unless we denominate it, as we formerly did, a catarrhal condition, not due to suppuration or infection of any kind. I would like to hear the opinion of the abdominal surgeons present, as to the proper management of a case of this kind, whether it would be better to submit a patient of this age with this sort of history to abdominal section, or to treat her on the old plan, which we have often done and which has often, so far as we know, cured these cases for years and until they have become mothers and subsequently have shown no signs of disease.

DISCUSSION.

Dr. W. H. Wathen: I wish to congratulate Dr. Irwin upon the treatment of the case reported without surgical interference. Such cases nearly always recover from the immediate effects without any operation. This trouble, from the entire history of the case and the history of the immediate attack, is acute. Her tubes, ovaries and uterus were undoubtedly previously in a healthy condition, and because of exposure of some sort, this local trouble began. While bacteria of some form are the prime factors in causing infection of the tubes and of the peritoneum, there may be other causes such as exposure during the menstrual period bringing on intense congestion, or traumatic injuries; but granting that it was infectious in its origin, there is no necessity for operation because the trouble is not sufficiently advanced to cause pus, and pus does not accumulate in tubes in this length of time; there might be salpingitis and some local pelvic peritonitis without an accumulation of pus; that would be an after result coming on in weeks, or months, sometimes in years. By the pathological processes familiar to abdominal surgeons, the tube becomes obstructed at the outer extremity and finally at its inner extremity, the accumulation of pus thus becoming sacculated. But this woman may have had no pelvic peritonitis, because salpingitis of an acute character might bring on all the pain with which she suffered, and the elevation of temperature and acceleration of pulse described by Dr. Irwin. I believe that this patient will recover without an operation at any time, and shall be surprised if in the future there is any accumulation of pus in

the tubes, or sufficient adhesions of the pelvic peritoneum to cause enough disease to justify a laparotomy.

Dr. J. G. Cecil: I heartily agree with what Dr. Wathen has said in regard to there being no occasion for surgical interference in this case. I believe the line of treatment pursued by Dr. Irwin is the one which is generally recognized as being correct and proper. I might ask if there is not a possibility of gonorrhœal infection?

Dr. Louis Frank: I believe in all these cases there is a possibility of accidental infection. I do not mean by this infection from coitus, but there is danger of infection from one member of the family to another, and this has recently been illustrated in an article written by a German investigator in the *Centralblatt für Bact. und Parisiten-Kunde.* In this article there are quite a number of cases reported of children, ranging from four to fourteen years of age, every one of which suffered from vaginitis. An examination proved that in every case the gonococci were found. It was finally ascertained that infection had occurred from one of the older girls having gonorrhœa, and the children all using the same bath-tub, the same towels, and some of the same linen, the infection had spread from one child to the other. If this is the case, and we have no reason to doubt it, I think that it is quite possible for all of these cases of vaginitis in young children to arise from gonorrhœal infection. Lately it has also been shown that specific organisms, such as the staphylococcus pyogenus aureus, may exist in a perfect healthy vagina without causing any trouble whatever. These organisms may also spread to the uterus and tubes and give rise to pus tubes. As for myself, I believe that nearly all pus tubes are due to specific infection. We may not be able in all these cases, however, to demonstrate the existence of the specific organism, because it is known that organisms die out on any medium in which they may be growing, provided this medium is by their continued growth rendered unfit.

Dr. I. N. Bloom: Concerning accidental infection—as a case in point: A child, five years old, was brought to me, suffering from what seemed to be simple vaginitis; no examination was made for the gonococcus because gonorrhœa was not suspected. The history of the case was that the child had been with her grandmother for two or three weeks, and there she had noticed a slight discharge from the vagina of muco-purulent material; she had developed a severe ophthalmia two weeks after her return. An oculist was called in and upon examination pronounced the trouble gonorrhœal ophthalmia. All history of gonorrhœal contact was denied by both the parents of the child and the grandparents, but accidentally the oculist discovered in a drug store, a prescription for a nitrate of silver solution to be used as an injection by the father, who had denied any history of gonorrhœa. Seven or eight weeks after I first saw the child, the father consulted me with the remains of a clap. Had it not been for the accidental discovery of the prescription in the drug store, it is probable that I should never have suspected anything more than simple vaginitis. I do not believe that a clear differentiation between simple and specific vaginitis has been demonstrated clinically in young children.

Dr. J. W. Irwin: I have very little to add in closing. The possibility of infection in this case is very remote indeed; if such a thing could occur it would be almost miraculous. So far as the treatment is concerned, thus far it seems to have been successful in relieving the trouble, and I hope the good results will continue until she is finally restored to health. I am gratified to see that the gentlemen who have spoken on the subject, agree with me in the management of the case. I have had a number of cases of this kind in former years, before the question of abdominal surgery for the relief of such conditions was spoken of very much, and, I believe, with fairly good results. In a great many cases permanent recovery resulted, while in a few the results were not permanent, and I have no doubt some of them, before this time, have lost the tubes, ovaries or womb.

He Had No Headache.

Mrs. Cawker—"Haven't you got a headache to-night, Ben?"

Mr. Cawker—"No, my dear."

Mrs. Cawker—"Oh I am so sorry that you have not! I bought a new headache cure to-day at a bargain, and I wanted you to try it."

THE WESTERN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Annual meeting, Kansas City, Missouri, December 27th, 1892.

[OFFICIAL REPORT.]

Dr. J. C. Barnes' (see page 517) paper on

ECLAMPSIA OF PREGNANCY.

DISCUSSION.

DR. HALL: That we are all in great doubt as to the cause of puerperal eclampsia in pregnancy goes without saying. I have had a great many cases, unfortunately, though, fortunately many of them have recovered. I think the majority of them were dependent upon renal trouble. However, we do come across different causes. Recently I was in consultation with a physician in this city, in a case where there was no evidence of renal trouble, and the patient went into a comatose condition after the second or third convulsion and never rallied, but died. I believe that in our progress, so far as the treatment of this disease and condition is concerned, we have sometimes, perhaps, progressed away from the truth. It is the fashion to lay aside venesection too often. In most cases, especially in plethoric cases, it is indicated. In fact I always use it in those cases.

In regard to the treatment there is a remedy not used in this case, which I have used and which has been used more largely by others, that is undoubtedly of great value, and that is the hypodermic injection of *veratrum viride*. That it has wonderful power in controlling these convulsions is unmistakable. I have given from four to ten drops hypodermically, frequently combining it with morphia, with the happiest results. Some physicians I have known to use as much as fifteen to twenty drops hypodermically. I used sixteen drops once and thought I had killed my patient. The amount of serum or bronchial secretion poured out was simply so enormous that I thought my patient would strangle before she could be relieved. But I do recommend and insist upon the hypodermic injection of veratrum viride. Just how it acts in controlling the pulse I don't know; but it is a fact that it acts promptly, efficiently and satisfactorily. Venesection, veratrum viride, morphia and chloroform, and the hypodermic injection of pilocarpine would certainly be indicated in this condition.

I wish to say also in regard to pilocarpine, my observation has been that in some of these cases I get a much more diuretic than diaphoretic effect; and I have frequently given it in cases where I desire a diuretic effect with success. I long since came to the conclusion that pilocarpine is much more valuable as a diuretic than as a diaphoretic, and in my own cases, if I anticipate any trouble, I give them pilocarpine in advance for the diuretic effect. Gentlemen, if you have not already noticed it, I believe you will find it worthy of trial.

DR. FRYER: From the standpoint of an oculist, I wish to say a word as to a point that I believe is often overlooked by obstetricians, and that is this, that in cases of pregnancy where we have trouble with the kidneys, it causes retinal difficulty; and that occurring during or before the seventh month of pregnancy, a very large proportion of those cases die from convulsions, or, if they get through their labor, they are afterwards blind from optic nerve atrophy. This is a point that I think every obstetrician should be aware of and keep in mind. I wish to concur in what my friend, Dr. Hall says in regard to pilocarpine in its action upon the kidneys. I have used pilocarpine hypodermically very largely, and I am sure in a large number of cases that we have the main effect upon the kindeys, and often little or no effect upon the skin.

DR. KING: Very soon after the reader began I mentally said, that patient died. That was not owing to the treatment at all, but from the fact that it is a very rare thing, after so many convulsions, or even half as many as noted in that paper, for such a patient to recover. My experience has been, and I believe the experience of others will bear me out, that where we succeed in curing the patient—

or relieving and saving her—it is only in those cases where we succeed in checking the convulsions at an early stage. I have seen but few cases of eclampsia, perhaps eight or ten, and it is my experience, where the patient had had eight or ten or fifteen convulsions before I got there, and that they continued afterwards for some time in spite of what I could do, the patient died. The patients I saved were those I saw early.

I believe there are two prime factors in the matter of relief. One of these is an early delivery. In the case of a pregnant woman with eclampsia, every possible effort should be made to secure delivery as soon as possible. The other factor is the elimination of the morbific element, whatever it is, through the alimentary canal and by venesection. I think it was unfortunate in this case that they were not able to get blood from the veins. It would have been justified if they had opened the temporal artery and got relief in that way. It was unfortunate, too, that they did not secure free action of the bowels. In cases such as this, where the convulsions have continued so long, and it is impossible to get that action otherwise, I believe that croton oil combined with sufficient doses of elaterium, every two or three hours, will do that work if it can be done, and I place a great deal of confidence in large evacuations from the bowels. My experiencce has been the same as that of Dr. Hall in that I rarely ever get diaphoresis. I have never tried pilocarpine for the reason that I have never seen a case of eclampsia since pilocarpine has been in use, and I hope I may never again see one.

Dr. Barnes: In closing I have nothing further to say except that I am getting a little more credit than I deserve. At that time, I was resident physician in the hospital. After we got the patient in, she was in charge of Dr. Fullerton, who did the primary operation on the cervix.

Dr. Schooler's paper on

UTERINE FUNGOSITIES.

(See page 571).

DISCUSSION.

Dr. Beattie: In the paper the writer has taken up this subject so fully, and his ideas coincide with mine so nearly that it does not leave very much for me to discuss. This condition is one that should be carefully looked into not only by specialists but by practitioners in general. As to the treatment of these cases, I have never had any experience with electrolysis, but from the writings of others, I conclude that good results have been derived in that way. I usually resort to the curette for the removal of these fungosities, and I use a sharp curette. It is not attended with much danger in the hands of an able gynecologist. When these growths are removed skilfully and carefully the endometrium, we know, is reproduced, and satisfactory results can usually be obtained. We may not only have the endometrium softened, but the softening may extend down into the body of the uterus. We may have a uterus that is in a sub-involuted condition; we may have a large amount of engorgement there. Where there is good deal of softening, very little pressure will take the curette into the abdominal cavity, hence it should be used with caution. Some operators never resort to the sharp curette.

Curetting should be done under strictly aseptic precautions and with an anæsthetic. I have curetted the cavity in my office, but it is something that I don't like to do. I would rather have the patient at a hospital or at her home, where she can be attended to properly and carefully.

Dr. Cordier: From the articles that appeared in different journals over the country, by men who are teachers in eastern cities, as well as some in our western cities, this subject, to me, is one of the highest importance in the whole range of gynecology. Sometime ago a noted writer, in condemning the removal of pus tubes and the opening of abscesses, etc., asserted that any obstacle we can place in the way of the laparotomist, we should do so. Now a declaration like that, coming from the source that it did, does an injustice to the progressive men of the country; it does an injustice to the patients of the country. These men are in positions of trust, so to speak; they are teachers; they are writers. Their writings are countenanced; they are accepted and recognized as being authorities. It remains for us, who disagree with their views, to overthrow these false theories. We are told that in septic conditions of the uterus, curetting is the thing to prevent extension of the trouble to the appendages.

We are told that cellulitus still exists in the pelvis as it did years ago, when it has constantly been demonstrated by operations and post-mortems that where we find inflammatory trouble in the pelvis, there we find diseased uterine appendages, abscesses, etc.

Now there are cases for curetting, but there is no doubt but such cases are few. Curetting is a major operation. It is an operation that one should undertake without knowing and having the ability to recognize whether or not he has diseased Fallopian tubes to deal with at the same time, because any interference with the uterus is sure to aggravate tubal trouble. In salpingitis it will convert a so-called latent condition into an acute condition, followed by the formation of pus with its direful results. As I say, this is certainly a major operation; it should not be done in the office of the physician. The patient should be put to bed; she should be prepared with the same care as though for a laparotomy. Scraping and cleansing of the vagina and uterine cavity should be carried out with just the same precaution, and as careful preparation as the largest abdominal operation known to surgery. The os should be dilated for two reasons, that your work may be safely done, and that the drainage may be good afterwards—a very important thing in these cases. In a large number of these cases where the curette is indicated, you will find it to be for retained placenta. Outside of that it is extremely rare to find a case where the curette is indicated. I desire, before this society, to condemn the reckless use of the curette; I mean by reckless use, the use of it in the physician's office. Within the last two weeks, I have known of patients alleged to have been curetted in the office of physicians, without anæsthetics, without dilatation of the os; they have been curetted and allowed to get up off the table and go shopping. It is a question in my mind whether they were curetted or not. If they were curetted, I don't believe they needed it; if they did, they didn't get the proper treatment, because it wasn't done correctly, for no man can do a curetting properly without an anæsthetic.

Dr. Van Eman: As I understand the gentleman's paper, he treats not of women who are bearing children and liable to have a portion of the placenta retained, but of that class of women, from forty-five to forty-eight, who have had from week to week and month to month, more or less hemorrhage from the uterus. They have been told perhaps by their family physician, and much oftener by the neighborhood women, that that is part of the penalty they pay for being women, and as a rule they neglect to call upon a physician, even their family physician. They will go further than that, and after the flow has ceased for a year or two, some of them think their youth is coming back to them. Now that is the class of cases, as I understand the paper, that indicate the use of the curette. Now I have one rule so far as that septic business is concerned, it is simply: Be sure of being clean yourself, of having a clean instrument, and that your patient is clean. If you stop short of that, I don't care whether it is in the office or in the hospital, you don't fulfill the whole law so far as surgery or gynecology is concerned. When you fulfill that law to the letter it doesn't make a great deal of difference where the work is done; that depends a great deal on the nature of the case. Now the first law that I lay down is, that every woman who has a protracted hemorrhage, the physician should decline to treat without an examination—just simply decline. Second, that an examination should be made with the greatest care, whether made at the office or the woman's home. It is often much more convenient to make it at the office than at the house. When it has been decided—and it can be decided very easily by the plan outlined—most any instrument, if it is clean—and if not, he hasn't any business to use that, or anything else to be passed into the uterus—may be used, and you bring out a little warty mass. You don't need to have half a dozen of these; one is sufficient to tell the practiced eye what is inside of that uterus. I have in mind now the case of a woman forty-seven years of age, who for six weeks had had a continuous hemorrhage, supposing it was she who paying the penalty for being a woman, and so giving but very little attention to it until finally she became so blanched and bloodless that she couldn't sit up in bed, and I was sent for. In that case there was no trouble at all to find out the condition of the uterus and to use the curette. I used the sharp curette—and I take it for granted

that the man who isn't fit to use a sharp curette isn't fit to use any curette. I could have done it without dilating the os, but I did dilate and under the influence of an anæsthetic, because it is easier to do the work and to do it thoroughly. A few minutes curetting absolutely and permanently cured this woman of her metrorrhagia. There isn't anything that would remove that but curetting, any more than it would remove a wart on your hand. It is an exuberant growth covering the uterus, and the sharp curette is the instrument to use. Be just as clean as you know how; if you don't know how to be clean, learn.

Dr. Adams: I heartily concur in this paper with the treatment which is advocated. The gauntlet has been thrown by Dr. Cordier, but unfortunately is outside the scope of this paper. I am a firm believer in the curette and its efficacy in certain circumstances and conditions. But referring to the paper and speaking to that alone, I don't believe in the use of the curette to gain any definite object and therapeutic effect unless under the use of an anæsthetic, and with all the precautions that you would enter upon a laparotomy. I believe that when you curette the uterus you should have a thorough dilatation; that you should have all the aseptic preparations necessary for any operation; that in the hands of him who has his mind at the end of his fingers, the curette is a safe instrument. In cases of uterine fungosities it is pre-supposed that the physician will examine the patient and take in all the surroundings before he enters upon that operation. He will see whether there is a pus cavity there. He will take every precaution—emptying of the bowels, thorough antiseptic irrigation, and then, if you please, antiseptic or aseptic packing—and you can enter the uterine cavity with a curette and take out uterine fungosities just as safely as you can enter the abdominal cavity and take out the ovaries or uterus. That is all there is to it.

Dr. Beattie: Dr. Cordier and Dr. Adams both spoke especially of dilating the cervical canal. Now my experience has been that when the endometrium is fungoid in character there is some change in the cervical canal as well. Nearly always when we have this condition of the endometrium, we have some inflammatory trouble existing in the cervix; and, when this is the case, if it has gone to any great extent, you will find, instead of the rigid os, a relaxed condition; you will find the cervical canal very much thinner than it is under ordinary circumstances, and as a rule you can introduce quite a large curette without any trouble, and to save my life I can't see why you want to dilate the cervical canal.

Cleanliness is certainly important. I listened this afternoon to one or two of our brother practitioners discussing the paper that was read, upon the mode of preparing patients and instructing medical students, and the taking care of women in confinements. It is nice to tell these things; it is nice enough to come before the society and say what you ought to do, but I tell you, gentlemen, you don't do it; you don't do it very often. And it is the same with reference to this particular operation. These things should be done at the hospital or they should be done at home under the most careful circumstances. But I say that cleanliness is all that we want; it is all that we want in the obstetric chamber; it is all that we want any place. And it is supposed that an ordinary physician is a man of a little more than ordinary calibre, and the men in the particular line of the diseases of women that I am speaking to—I mean who have devoted some special study to obstetrics—it is supposed that they understand these things; it is supposed that they will not undertake a case unless they have washed their hands thoroughly and have taken the other precautions.

Dr. Ward: I desire to correct Dr. Beattie about one thing, if he is referring to the physician-in-charge of the Preston Retreat; and if he means to state that he doesn't carry out the minutia that he describes. And I will ask him to kindly go to Philadelphia and observe, at my expense—that is, if he finds there is any error in that matter. I think you will be very tired, Dr. Beattie, when you see the minute details—when you see the work there—and say you can never do it yourself.

Dr. Beattie: I don't refer to my friend, Dr. Price. I think he does not go so far into the details with reference to some of the minor things in obstetrics, as my friend, Dr. Berger. I hope Dr. Berger is here to-night; I wanted an opportunity to answer his remarks this after-

noon. It was the way he had his medical students prepared for the obstetrical room. I tell you, gentlemen, when you tell me these things, I know better; I have been a medical student myself, and I know that they don't—at least when you give them bichloride of mercury and the other antiseptics—they don't use them, and they have just as good results as the men who are so very careful. I visited the Preston Retreat this summer, and I was very highly pleased and certainly encouraged. I was delighted with the conveniences and details of that institution; and it was certainly not with reference to that institution that I was speaking.

Dr. Price: This is a very interesting subject and has received considerable attention this evening. It would seem that some gentlemen have limited the discussion to about one-half of its territory. If the doctor proposes to confine his use of the curette in this discussion to so-called fungosities and vegetations, papillomatous growths, polypi and the like, of course we can't take that liberty with his paper and with the curette that we should like. I feel that the curette has been used with very considerable freedom and recklessness—used without clear and recognized indications. I think about all the gentlemen have indicated that fact in their discussion, that it has been used by some without a recognition of clear indication. We well know that we can have profuse and irregular bleeding and discharge from a crop of sago granulations and papillomatous growths or fungosities, if you please. Just here, I may say, I am not so familiar with these so-called fungosities. I don't believe that the uterine cavity is so productive of that form of vegetation. You commonly hear in societies men speaking with great freedom about fungosities, but if you look them up and seek for them pathologically, you will often fail to find them. I believe in cleaning the cavity of an unhealthy uterus or of a dirty one, but first I must be assured that it *is* an unhealthy uterus or that it *is* the seat of some growth of that nature. To-day, for instance, I made a demonstration; I removed a uterus from a woman fifty years of age, who had bled profusely and irregularly, had had a copious discharge and had received local and general treatment without relief. After removing this uterus—incising it—I remarked before one or two present, that my finger or towel or a little piece of gauze would not wipe away all unhealthy condition found in the cavity. This uterus was the 101st. that I have removed by supra-vaginal hysterectomy, and in that group of 101 I have never removed a uterus that had anything in it that should be scraped away by the curette. And out of a series of some fifty or sixty vaginal hysterectomies, my experience stands precisely the same. I have used the curette freely in intra-uterine sarcoma, and that is not a rare disease. The cervix in many cases is perfectly healthy; there isn't the semblance of disease; the fundus is so soft and cheesey that you could scrap away almost the whole cavity of the uterus with the curette. We have no other means of clearing up the diagnosis in this group of cases except with the curette. We have profuse, irregular bleeding, offensive discharges suspicious in the highest degree; but to settle the question as to the precise nature of the trouble it is necessary to use the curette. It is also necessary to use it in mucous polypi and sago granulations, and in the remaining debris of a neglected abortion or miscarriage.

I wish to speak especially of this group of cases, the free and indiscriminate use following abortions or miscarriages when there is a suspicion of a membrane or a portion of the placenta remaining. You all very well know that there is a little gynecological wave going over New York at the present time, an endometritis wave. We have had these waves in gynecology for years, and just at present in New York everything is endometritis. It matters not what is the nature of the trouble in a woman's pelvis, the curette is used. I found last summer, while dealing with a few of these cases, having seen a few of them in New York—and specimens presented—for instance the puerperal or abortion cases—later I had to remove angry and vicious specimens from the pelvis, together with quantities of lymph, pus and muddy fluid independent of the specimens removed. I could not permit these cases to go without saying something about the New York treatment. They curette the uterus and pack it with gauze.

About the time I was dealing with some of these cases, a young physician assisting the coroner came into my office and asked for some practical work in obstetrics. I

asked him how he was spending the summer. He said he was following the coroner, and went on to tell me that they had an interesting case out at Blockley Hospital — criminal abortion; that they had some one arrested and locked up. I asked, "Did you have a *post*?"—"Yes."—What did you find?"—"We found all the intestines matted together, pus and lymph and everything glued together."—"What had been done?"—"Well, the uterus had been curetted and we found it full of gauze." Probably I am not confining myself strictly to the paper but I just cite this case—and I could cite a great number of them—to show the reckless use of the curette without recognizing the precise nature of the trouble.

Dr. Halley: I think that waves of fashion pass over the professional world as well as the social world. I know it does. I think the present wave of using the curette is one of them. It is in the hands of everybody who is pretending to do anything at all either in obstetrics or gynecology—and pretty near all of us do something of that kind—and every one thinks he has a warrant to go in and scrape the womb. It is a wonder one doesn't scrape her mouth out when she is bleeding at the gums; it would be about as sensible. I believe there is a great deal of harm done by it.

But I don't rise to discuss the paper in this way. Some twenty years ago, it was suggested to use nitric acid in the cavity of the womb for the treatment of those fungosities, and it was a treatment that the inventor declared gave him excellent results. In the small number of cases in which I have used it—and I have used it in as many cases as I found occasion for—I obtained most excellent results. Dilating the cervix and, in place of curetting, washing the cavity of the womb with some cotton. This, of course, after making the preliminary preparations. After that is done, in place of using the curette, use a piece of cotton or sponge saturated with fuming nitric acid. You can do all and more than you can with the curette.

Dr. Van Eman: Just let me take the floor to say that the "more" that you can do with nitric acid is just what I object to.

Dr. Schooler: Some objection has been found with the name given to the growth for which the curette is designed to be used. It is used generically for vegetations that can be relieved by that method. Now I saw the uterus that was removed to day, and saw the condition of the endometrium. It was not different from that of many others that I have seen, and I don't know what indication there would have been for the curette in that or any other fibroid tumor, unless you wish to use the curette first and make the diagnosis afterwards.

But if I intended to have any point to the paper, it was to make note of suitable cases, to limit the use of the curette to that class of cases entirely and not to go beyond that. It is a comparatively easy matter to ascertain whether any of these growths exist or not. If none of them exist, there is no benefit derived from the use of the curette except to scrape away the debris or remaining portion of a placenta after abortions or miscarriages; or sometimes where the placenta has not been properly or entirely removed after a normal parturition. The use of the curette in malignant growths, as a matter of course, is only temporary, and perhaps is more frequently used as a means of diagnosis than otherwise.

I agree with Dr. Beattie that dilatation is not very often necessary in these cases, although occasionally cases will be seen where dilatation is necessary before you can bring away anything of any size or importance with any comfort to yourself.

Now so far as fashions are concerned, that I suppose has allusion to the reckless manner of using the instrument. That, of course, I condemn as well as others; and as to the use of nitric acid, I agree with my friend on the right here (Dr. Halley), that if that should become the general practice to-day, there would be a great deal more done with it than has been done with almost any instrument in the last quarter of a century, and generally be to the detriment of the patient. Of course, I don't wish to be understood as saying that these growths cannot be destroyed by nitric acid, or that any other growth cannot be destroyed by nitric acid if applied in a sufficiently concentrated solution; but that strength would make it dangerous and haphazard when applied by persons without proper knowledge and experience.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, APRIL 22ND, 1893.

EDITORIAL.

"MUCH ADO ABOUT NOTHING."

"Are you good men and true?"

"Yea, or else it were pity but they should suffer salvation, body and soul."

"Nay, that were a punishment too good for them, if they should have any allegiance in them, being chosen for the prince's watch."—*Shake.*

Under the alluring title "An Experiment in Castration" the *New York Medical Record* editorially gives the following unique item of news:

"An interesting experiment has suddenly come to grief at the Norristown Insane Asylum, Pa. Some of the medical staff became much impressed with the value of castrating women as a therapeutic measure in insanity. The consent of the trustees being secured a surgical ward was established, and fifty patients selected as being cases likely to be benefited by the operation. The process of oöphorectomy was begun, and went on swimmingly until the fifth case was reached. The fifth patient died, and a pause in the surgical work ensued. The Lunacy Committee of the State Board of Charities took up the matter, an investigation was begun and a report made. This report condemns the operation of oöphorectomy, except in cases of gross disease which absolutely demand extirpation. The subject of the personal rights of the insane in the matter was dealt with by a legal member of the Committee, who offered this official opinion:"—(Here follows the legal member's invaluable opinion).

The editorial comment would be a very good one if it were not a misfit.

As it is considerably over six weeks since the affair was fully exploited, it would seem as though the information ought to have reached New York at this date, even if it travelled *via* Chicago.

However, the *Record* is not the only medical journal that has just obtained the news of last December. The following letters, which appeared originally in the *American Journal of Insanity* for January, 1893, under "Correspondence," have re-appeared in a variety of other journals of more recent date—published by request. Most, though not all, of these journals appear to have missed connection with passing events, and are not yet

aware that these effusions are criticisms of "castles in Spain."

To the Editor of the *American Journal of Insanity*, Utica N. Y.:

My Dear Doctor: Thinking you might desire to publish three letters bearing on the papers sent you recently, I enclose you copies of letters received from Drs. Chapin, Goodell and Levick, all of this city. I would be glad if these could appear in the same issue of your Journal as the reports you have.

Very truly,

Thomas G. Morton.

Dr. G. Alden Blumer.

Philadelphia, 12th Mo. 23, 1893.

Dear Doctor Morton:

The portion of the forthcoming report of the Committee on Lunacy on "Removal of the Ovaries as a Cure for Insanity" and the opinion of Commissioner Barlow on the legal relation of such operation, kindly sent me for perusal, are herewith returned.*

I can hardly express in words the satisfaction and gratification I experienced on reading your paper.

First, I felt to thank the Committee and the State Board that they have come forward to exercise the powers of their office to save the hospitals, and I may say our profession, from what threatened to become a scandalous proceeding. To erect an hospital, or propose one where women were to be castrated in companies of fifties, with the hope of a cure of insanity, would be generally regarded, in the present state of meagre knowledge upon the subject, as revolting.

There is no sufficient experience nor knowledge to warrant an operation of this nature, and I am sure that in this opinion you will have the support of the entire profession and the community. I will further add that the paper is so logical, and, as to the rights of all concerned, cannot be overturned.

In a case in England, Dr. Robert Barnes declined to perform the operation without the consent of the Commissioners of Lunacy.

Several applications have been made at this hospital for permission to perform the operation here, upon patients who were insane. It has not been the policy of the hospital to encourage operations of an experimental character, founded upon hypothetical conditions, upon the insane.

I am sure, for these reasons, and for the moral and legal questions involved, the managers would be in accord with this sentiment if the question were submitted to them.

As a physician of an hospital caring for the insane, I would, under no circumstances, assent to the performance of the operation discussed by your Committee upon a patient, if the responsibility devolved upon me.

Hospitals for the insane might easily lose a portion of the slender hold they now have upon the public and friends of patients, if it were understood that the patients were subjected to experimental operations of a hazardous nature.

Believing the action of your Committee and the State Board is in the direction of a wise exercise of its prerogatives, I shall support it and conform my action to it.

I remain, sincerely yours,

John B. Chapin.

December 14, 1892.

Dear Dr. Morton:

In the main I agree with you in the points which you have made. I believe that the whole business of removing the ovaries has been horribly abused, and I am glad that you have taken such a firm stand.

I have written to Dr. W. H. Baker, of Boston, for an account of his trial for removing the ovaries of a crazy woman, and I will send it to you when it reaches me.

Dr. Francis Imlach was ruined financially, professionally, and in his health by an analogous law-suit.

Very faithfully yours,

William Goodell.

Dear Dr. Morton:

I have read with great satisfaction the paper kindly sent me by you. With the sentiments there expressed I heartily concur.

Insanity is a disease of the brain, not of some organ remote from it. And when manifestations of insanity seem to be especially associated with functional dis-

*This "portion" was withdrawn by the Board of Public Charities and its unauthorized publication formally denounced—Ed.

turbances of some one organ, this disturbance is secondary to the brain disorder, not the cause of it.

One of the most frequent phenomena in the insane is seen in disturbance of the digestive function, an *excessive* desire for food or a *depraved* appetite—*boulimia* and *pica*. Even pins, needles, stones, etc., are eagerly swallowed by such patients. But no one has ever proposed to cure this disorder by removing the stomach, or other organs concerned in digestion. The brain disorder is remedied and this functional disorder passes away. So, too, it is with the ovaries. To remove them *for the cure of insanity*, is, in my opinion, unscientific from a medical standpoint, unjust to the helpless insane, and I am glad it has been pronounced to be, by a high legal authority, an illegal if not a criminal procedure.

Very truly yours,

JAMES J. LEVICK.

December 26, 1892.

These three letters are interesting "voices out of the past." Two of them we lay aside without comment. But the first, on account of the official position of the writer and in no way because of his personality, must needs bear criticism.

"*Come hither, neighbour: God hath blessed you with a good name: to be a well-favoured man is the gift of fortune; but to write and read comes by nature. . . . . Well, for your favour, sir, why, give God thanks, and make no boast of it; and for your writing and reading, let that appear when there is no need of such vanity. You are thought here to be the most senseless and fit man for the constable of the watch.*"

It ought to be easy for the writer of this letter to find his affinities in an asylum for mental cripples. The letter strikes us as a large exhibition of moral cowardice, professional jealousy and perverted cerebration.

The author is greatly rejoiced that, "the hospitals and the profession are saved from a scandalous proceeding."

The only thing proposed was to treat the insane as others are treated. To operate for clearly and well-marked disease. "There is no sufficient experience nor knowledge to warrant an operation of this nature."

There is not much experience to be sure, but of knowledge there is abundance and most positive in character. But so long as superintendents take the position that "under no circumstances" would they consent to the performance of necessary operations for the relief of disease, we are not likely to have a very large amount of experience. Hospitals *ought* to lose the slender hold they now have upon patients more easily and quickly by failing to do their plain duty, than by resorting to the clearly indicated surgical treatment, by and with the consent of guardians and friends.

In Tukes' Dictionary of Psychological Medicine, Vol. II, pp. 876, Dr. Robert Barnes, who writes the article, says: "The indication to remove the ovaries was to our judgment decisive. We were supported by the assent of her guardians, of an eminent hospital physician and of a distinguished alienist, but we declined to undertake the responsibility without the sanction of the Commissioners in Lunacy. *The patient continued insane.*" He goes on to say: "Sir Spencer Wells, in a case somewhat different, being consulted as to the legality of operating upon a lunatic, asked Sir Wm. Harcourt, then Home Secretary, who said: "If she is incapable of judging for herself, treat her as if she was an infant." So the operation was done, the patient recovered and married. Surely, (so Barnes concludes) this *dictum* is good sense as well as good law."

And earlier in the article he says: "One lesson to be deduced from this apparent conflict of experience is that the question demands earnest and extended inquiry." The lesson Dr. Chapin deduces is "Do nothing!"

When he says that "under no circumstances would he permit such an operation" he evinces unfitness for the position

he holds. If such a spirit as his is to predominate in the institution under his control, let them no longer call it a hospital. It is rumored that he and his colleagues do sometimes call in a consulting gynecologist, but a great majority of their female patients are never examined. In 1885, a woman was received at the Norristown Asylum coming from under the care of Dr. Chapin, *et al.*, at the Pennsylvania Hospital, where she had been for a long time. She was suffering from multiple carcinomatous growths attached to both uterus and ovaries. She lived only a few months and probably could not have been helped at an earlier stage, but her friends thought it very strange that the nature of her trouble had not been inquired into at the Pennsylvania Hospital. In like manner another patient was received at Norristown a few months ago, who had been three years at the Pennsylvania Hospital. She has some abdominal tumor of large size, presumably uterine fibroid, but Dr. Chapin could furnish no information on the subject when applied to. And this is a fair sample of common hospital treatment for the insane.

There is no general hospital where any well-informed medical man would be willing to send one of his insane friends, knowing they would receive hospital care and treatment.

A short time before the death of Dr. Kirkbride, one of Philadelphia's most eminent surgeons was speaking of this lamentable condition of affairs. He said: "I would not know where to send my wife or daughter, and if Dr. Kirkbride dies, I know a dozen men who will go before that Board of Managers and demand that this state of things shall cease." Evidently it has not ceased. They continue to take patients to board in a highly respectable way, but that is all. Dr. Chapin's own words convict him.

The writer of that letter will never be compelled to join in the piteous lament of Dogberry: "Dost thou not suspect my place? Dost thou not suspect my years? —O that he were here to write me down, *an ass*! But, masters, remember, that I am *an ass*; though it be not written down yet forget not that I am *an ass*.—No, thou villain, thou art full of piety, as shall be proved upon thee by good witness. I am a wise fellow; and, which is more, an officer; and, which is more, a householder; and, which is more, as pretty a piece of flesh as any is in Messina; and one that knows the law, go to; and a rich fellow enough, go to; and a fellow that hath had losses; and one that hath two gowns and everything handsome about him.—Bring him away. O, that I had been writ down—*an ass*!"

He has allowed his writing and reading to appear "when there is no need of such vanity." Had he exercised due discretion and not allowed his credulity to place him at the mercy of "bunco players," he would speedily have learned of the action of the Board of Public Charities, repudiating the course of the Lunacy Commission, whose erroneous information and unauthorized, premature publications had placed the Board in such a stultifying position; and that the Board had unanimously rescinded that portion of their report bearing on the subject, and, that it had not been published with their knowledge and approval.

All this and more has been set forth in the "Reporter," the last mentioned action being announced in the issue of March 11th.

"Were you ever caught in a sudden squall?" asked an old yachtsman of a worthy citizen. "Well, I guess so," responded the old man. "I have helped to bring up seven babies."

Two Girls—"Please sir, do you keep excursion pills?"

Chemist (equal to the occasion)—"Yes, we have some very fast ones."

TRANSLATIONS.

PHYSIOLOGY OF THE HEART.†

Germain Sée (*Le Bull. Mèd.*, Jan. 25) says that the cardiac system comprises three distinct elements, the muscle, the vessels and the nerves, which are themselves of three orders:

1. The cardiac muscle, or myocardium, governs the entire circulation, since, as proven by recent observation, it exercises an absolute and independent automatic power, scarcely modified by the functions of the other organs of the motor apparatus of the blood.

2. The vessels, especially the arterioles which may be taken as a type, constitute cylinders, tubes at times elastic as rubber, and contractile as smooth muscular organs; the elasticity, a passive property, when put into operation, furnishes an obstacle to the progress of the blood; the contractile activity reduces the calibre of the vessels and retards the circulation. The vessels are not, therefore, as has been recently suggested, a peripheral heart; the contrary is true; they are most often the antagonists of the heart, or at least, obstacles to the course of the blood (Dastre and Morat, 1884). This is especially seen when the tubes have lost their elasticity, as in arteritis, sclerosis, atheroma, and especially in calcification, where the tubes become rigidly, inflexible as incrusted canals.

3. The nervous organs are of three classes. The first comprises the ganglia to which has been ascribed the power of motor innervation, or the faculty of arresting motion. The most recent works have justified this hypothesis, so generally admitted. None of the ganglia, neither Ludwig's, Bider's, nor Remak's, possess an impulsive property. The heart is endowed with automatism and antonomy. Its movements, once established in their rhythm and according to the laws of activity of muscles, may be augmented in number by the sympathetic nerves, called accelerators, radiating from the spinal cord, or diminished by the indefinite nerves, called depressors, radiating from the medulla oblongata; this is the role of the second series of nerves.

The last series is, on the contrary, a true regulator of the tubes of escape. It is composed of two classes of nerves; in the first place by the vaso-motor *constrictor* nerves, which have their center of origin in the bulb; when these nerves are active the vessels which they supply contract and impede the transmission of the blood towards the periphery. If, on the contrary, the vaso-motor constrictor center, the source of the nerves of this name, becomes paralyzed, all the vessels of irrigation are relaxed; the vaso-motor paralysis has relaxed their walls. The other form of vaso-motor nerves is that known as the *vaso-dilators*; by their excitation they produce dilatation, the same effect as is produced by a paralysis of the vaso-constrictor center. The paralytic relaxation of the vessels or their true dilatation tend in certain conditions to a favorable result for the heart; they are the indirect means of progression. The constrictor nerves, stimulated in their center or in their periphery are, on the contrary, the means of reduction of the circulation.

The ganglionic masses and their respective roles in the functionating of the heart, have been variously interpreted and recently discussed in a new sense. Their situation was discovered by Woldrige (1883) and Tigerstedt (1884); their functions were gone over by His and Romberg in 1891, and definitely fixed by Krehl and Martins recently (Sept. 1892). The extra-cardiac nerves coming from the vago-sympathetic nerve, pass to the posterior surface of the bulb of the ascending aorta, and are directed towards the upper surface of the pulmonary artery. There, they divide into two networks, one of which, called bulbar, descends towards the ventricles, and the other, or anastomotic network, passes between the bronchial tubes and the pulmonary artery toward the auricles to constitute the auricular plexus. There are, therefore, a bulbar and an auricular network, together with an anastomotic plexus. The ganglia are collected in large number at the point of division of the bulbar and anastomotic plexuses; they are well surrounded by large arteries. Below the point of separa-

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

tion of the coronary artery, which, in the rabbit, enters immediately into the cardiac muscle, there are but few ganglia situated at the lower border of the arterial cone.

The ganglia are everywhere nestled in the lax cellular tissue of the pericardium, or its prolongations between the aorta and pulmonary artery; they penetrate into the partition between the auricles, never into the compact muscular bed. The ventricles have only a few isolated ganglia situated on the upper border of the arterial cone. The interventricular wall in particular is deprived of ganglia; it is this part of the wall which is the seat of the probable center of coordination which Gley and Sée have described after Kronecker and Schemey.

Sée concludes as follows:

1, The cardiac ganglia do not possess most of the functions which have been attributed to them; they certainly are not, as has been said, the vehicle which governs all and in all. They are slight organs of sensibility.

2, It is the cardiac muscle which is supreme; it is not only the automatic motor of the circulation. After various diminutions in its power, it may itself repair and compensate for all in overcoming resistances, in emptying the surcharged ventricles, and all this by the over work which the heart executes without having recourse to nervous influence.

3, The heart has in itself a dynamic reserve, and it is from this that its enormous power comes; the alterations of this organ should be taken in consideration when there is a local lesion, valvular or not, or a lesion of general origin. In one or the other case it is necessary to attend to the ultimate changes of texture rather than to have recourse to the common explanation of fatigue or dilatation of the heart, which cannot be denied.

4, Functions of the ganglia and nerves. The researches of His and Remberg, which have preceded those of Krehl and Martins, are still most explicit in certain points. The nerves of the heart, they say, do not develop with the heart, in the heart, but they proceed from the vagus nerves and from the sympathetic, to penetrate into the heart.

The cardiac ganglia are not sympathetic, and without doubt constitute centers of sensibility; they have no influence upon the arrest or upon the acceleration of the activity of the heart.

5, The cardiac muscle, on the contrary, works without any nervous excitation—it works automatically, and by its proper force; it is in the heart itself that it finds the impulses to its activity. The idea of a cardiac nervous center, itself automatic and motor, is therefore without foundadation.

A CASE OF BIRTH IN THE COFFIN AFTER MATERNAL DEATH.*

A case reported in (*Kreisphysikus zu Schlochan in Westpreussen*, Bd. 3, 1893) by Bleisch has caused the author, Dr. Moritz, to report one of similar character. The patient, aged 35, fell in labor on Sunday, June 19th, at 12 P. M. She was attended by a mid-wife who examined her while having severe contractions on the lap of the husband, but decided that she could not deliver the child. She was brought to the edge of the bed, the mid-wife again using various manipulations with no effect. While she distinctly felt the head, according to her statement, she was still unable to deliver. At 7 A. M. the patient died without having given birth to the child. The funeral took place three days later. Owing to a denunciation made by the gendarmes on the 5th of July, against the mid-wife as a causative factor in the death of the patient, the corpse was exhumed thirty-eight days after death and thirty-five after burial.

(*a*). *External appearance.* The female corpse 157 cm. long, well-supplied with fat; muscles well-developed. The skin is generally moist; whitish-gray color; face greenish-gray and swollen. The back, breast and abdomen greenish-gray and moist; and the inner sides of the thighs are soiled and grayish-red. The entire body is covered with blisters varying from the size of a pea to that of a

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

hen's egg, and filled with decomposing gases and moisture. The odor was unpleasant; the upper and lower extremities freely movable. The eye-balls are softened and deeply retracted. The lips bluish-black and moist. The abdomen markedly distended.

Between the thighs lay the corpse of a male child, 2¾ kg. weight, 49 cm. long, and otherwise having the appearance of a fully-developed fetus. The child lay with its back upwards and the head near the knees of the mother, facing the left side of the mother. The cord was 47 cm. long, the size of a lead pencil in thickness; bluish-black in color and soft in consistence. The placenta was a bluish-black softened mass, and was almost entirely extruded from the vaginal tract. It was attached in one portion to the uterus, this latter being almost entirely inverted, and presented a large mass the size of a man's head. There was, therefore, total eversion of the uterus together with the vagina. The mucous membrane of both presented a smooth, slimy, reddish-gray surface with green spots, only at the place of attachment for the placenta was the surface rough and greenish-black. The labia majora were almost obliterated, and but traces of the labia minora could be detected between the former and the uterus.

(*b*). *Internal examination.* The cranial cavity: In opening the cavity the brain was found to have changed to a thin, reddish-gray, offensive mass.

The thoracic and abdominal cavity: The thoracic organs show nothing more than advanced stages of decomposition. The intestines contained in the abdominal cavity are markedly distended. The uterus cannot be found in the abdomen. The region where the uterus had been is marked by an oval opening 3 cm. long, and a-half cm. wide. On the margins of this opening are seen radial folds. Pressure upon the inverted uterus causes a discharge into the abdominal cavity of foul-smelling gases, which causes collapse of the organ and permits its reposition. The walls of the uterus are about 6 mm. in thickness, and uninjured. The conclusions arrived at are the following:

(1). The patient died previous to delivery. (2). It was not possible to determine definitely the cause of death by section alone, since decomposition had advanced too far. (3). It is impossible to tell if the patient died of hemorrhage, or if death was caused by a third person. The explanation for the birth in the coffin is that by generation of the decomposing gases the child was expelled from the uterus by mechanical pressure.

In closing the author states that in his case there was a certainty that the patient died before giving birth to the child, that at the time of burial, three days later, the child was still in the uterus, and, for that reason, *post-mortem* contractions could not be thought of; while on the other hand the presence of decomposing gases in the abdomen of the corpse were sufficient to cause the expulsion of a normally presenting fetus.—*Vierteljahr. f. gericht., Med.* January, 1893.

He Kept Grand Medicine.

In a Scotch village, where a young doctor had lately started practice, a workman had the misfortune to get his finger bruised badly in one of the mills. A doctor was sent for, and on properly dressing the finger the man nearly fainted. He was asked if he would take a little spirits to revive him. "Mon," he exclaimed with feeling, "that wud just be the very life o' me!" The doctor gave him a good glass, which he greedily swallowed, and on recovering his breath his first words were: "Well, doctor, I kin unco' little aboot yer skill; but, mon, ye keep grand medicine."—*Detroit Free Press.*

A Gentle Laxative.—A druggist received a ℞ some time since, which called for Hydrargyrum Chloridum Corrosivum in doses of five grains every two hours.

The startled druggist sent the prescription back by the small boy for correction. A few minutes later the white hat, curly locks and Apollo-like figure of Dr. Blank appeared, and the voice from under the hat spake thus:

"What's the matter with that? Don't you think I know what I mean? That prescription means what it says."

"Might I venture to ask, doctor, what effect you expect from the drug?"

"The effect," returned Blank, "will be that of a *gentle laxative*, merely a *gentle laxative!*" Druggist fainted.

BACTERIOLOGICAL NOTES.

A NEW METHOD OF STAINING THE CAPSULE ON THE PNEUMONIA GERM.

The demonstration of the capsule on the pneumonia germ is sometimes attained with considerable difficulty, while at others, it is brought out very nicely by the ordinary methods of staining. Welch (*Johns Hopkins Hospital Bulletin*, Dec., 1892) in an article on the etiology of acute labor pneumonia, has given a method for staining the capsule in those cases where it is not easily demonstrated by other methods. "Cover-glass specimens made from the tissues without water, are treated first with glacial acetic acid, which is at once allowed to drain off and is replaced (without washing in water) with aniline-oil gentian-violet solutions. The staining solution is repeatedly added to the surface of the cover-glass until all of the acid is displaced. If now the specimen is washed with a saturated aqueous solution of common salt, and is examined in this solution, it will be seen that both coccus and capsule are uniformly and deeply stained and cannot be differentiated. If water be used instead of saturated salt solution, the capsules are decolorized, sometimes only in part when they can be clearly recognized, but often completely, and they may entirely disappear by using weaker solutions of salt. It is possible in all cases to differentiate the capsule if it is present. The strength of the solution best adapted to different cases varies. Often the ordinary physiological solution suffices. A generally useful strength is 2 per cent. The specimens are to be examined in the salt solution. When mounted in balsam the capsules do not always remain distinct. The capsules may appear stained throughout or only their outer margin may be stained.

This method of staining was worked out on the supposition that the capsules are composed essentially of mucin which is precipitated by acetic acid and, when thus precipitated, is insoluble in concentrated salt solution and swells up in water. The chief disadvantages of this method are the difficulty of avoiding precipitates of the dye, and the alterations in the cells and other elements, but in difficult cases it will serve a useful turn, although less violent methods when applicable are to be preferred."

THE VIABILITY OF THE CHOLERA BACILLUS ON VARIOUS FOOD STUFFS, Etc.

Uffelmann (*Berliner Klin. Wochenschrift*, 1892, No. 48) records the results of his investigations on the viability of the cholera germ on a considerable number of food stuffs and other articles. These observations were made for the purpose of gaining information as to the danger of transferring these bacteria in the various articles such as milk or butter, meat, fish, bread, vegetables, fruits, etc. The results were as follows: In water the bacilli remained alive for from five to six days; in milk for about three days; on the surface of bread exposed to the air for about twenty-four hours; between the slices of bread kept moist, for about eight days; on cooked meat kept moist for eight days; in butter for three days; on an apple for four days; on paper for about thirty-six hours; on copper and silver coins for only ten minutes after they were dried; on dry clothing for four days, on moist linen for twelve days or longer. The dry skin of the hand preserved the germs alive for more than an hour after contamination.

Uffelmann also showed that house-flies were capable of infecting nutriment media with the comma bacillus two hours after walking over the dejecta of cholera patients. These observations show the importance of drying all infected material and the great value of air and sunshine in disinfecting after this disease.

ABSTRACTS.

ADMINISTRATION OF CHLOROFORM AND THE DANGERS INCIDENT THERETO.

J. D. Balfour, M. D., London, Ont., discussed the subject under two headings:

1. The dangers of chloroform, their causes and treatment.

2. How to avoid these dangers, *i. e.*, the best mode of administering chloroform.

For the sake of convenience we will speak of three stages in the administration of chloroform: (1) Excitement; (2) Complete anæsthesia or unconsciousness, and (3) Profound narcosis.

Dangers from the Lungs.—The first stage, or that of excitement, is the most dangerous, as more than half of the deaths from chloroform occur during this period before the operation is begun. One source of danger here is the liability of asphyxia from direct obstruction to the entrance of air into the lungs.

This condition may be caused by stertor, falling back of the tongue and depression of the epiglottis, spasm of the glottis, nasal obstruction, and also by the administrator, in not allowing sufficient air to enter to maintain the respiratory movement.

By stertor here is not meant the ordinary palatine stertor of snoring, but a stertor caused by the vibration of the epiglottidean folds which approximate so closely sometimes as to endanger life. This condition is recognized by the peculiar noise, the lividity of the patient's face, and from the fact that although the respiratory movements may continue, no air is entering the lungs, as may be ascertained by placing the hand over the patient's mouth.

Falling back of the tongue and depression of the epiglottis is another form of direct obstruction to the entrance of air, one, however, easily recognized and somewhat frequent, occuring several times in my experience. Both these forms of obstruction are removed by turning the patient on the side and drawing forward the tongue, this operation relieving the stertor in the larynx and raising the tongue and epiglottis. Spasm of the glottis is another form of direct obstruction; here the patient's face becomes livid, convulsive movements ensue, the respiratory movements continue, but no air enters the lungs. When this condition is present the chloroform must be stopped at once, and if breathing does not take place directly, artificial respiration should be kept up until the patient is restored. If sufficient air be not allowed to enter the lungs with the chloroform, the chloroform itself becomes a direct obstructing agent and causes asphyxia by excluding the air.

Dangers from the Heart in the First Stage.—By far the most important source of danger in this stage is the risk of an early, sudden and sometimes fatal syncope. As to its cause authorities differ widely.

It seems sometimes to be induced by the act of vomiting, but whatever the cause, this much is certain, that the first effect of chloroform is to stimulate the higher nerve centres in the medulla, so that their functions are disturbed; they are intoxicated, so to speak, and while they are in this condition syncope is liable to occur.

Its advent is sudden, the face becomes pale, a few short shallow breaths, and the heart stops beating, although the respiratory movements may continue. It is, however, a comfort to know that syncope at this stage is not nearly so dangerous as when it occurs later on during returning consciousness.

If the patient's head be lowered, and artificial respiration at once resorted to, it will generally, some say always, restore the patient.

Nitrite of amyl is of service here, especially if the syncope be caused by a reflex inhibition of the heart.

As stated before, there is great danger as long as the stage of excitement lasts. Now, the stage of excitement will not cease until the reflexes are abolished, and as chloroform is given for the express purpose of paralyzing these centres, clearly the safest method is to keep up a sufficient and continuous administration from the first until this effect is produced.

It is a dangerous procedure to remit

chloroform in this stage. I would like to emphasize the statement that I hold the best way to administer chloroform in the first stage is to commence cautiously, and then to continue with a hand neither timid nor reckless.

We will now enter the second stage, that of complete anæsthesia or unconsciousness.

If the chloroform is now continued without abatement dangerous symptoms will soon be seen. The pupil becomes suddenly fully dilated and fixed, the globes prominent, the respiratory movements weak, irregular and sighing, the heart beats irregular and feeble, the face very pale; the commencement of these symptoms marks the beginning of the third stage, or that of profound narcosis.

I stated that the stage of excitement was the most dangerous period in the administration of chloroform. But almost equally dangerous, if unfortunately it becomes necessary to enter it, and sometimes it is necessary, is the stage of profound narcosis.

It is clear, therefore, that the object of the administrator during the operation should be to avoid these two danger points; on the one hand not to allow the patient to so far recover as to allow the reflexes to operate, and on the other to be careful not to endanger the centres of respiration and circulation by too much chloroform. But this is not always easily accomplished.

The best way, however, to guard against the first danger is to frequently examine the eye, and any movement the patient may make, for symptoms of returning consciousness and reflex action.

If the pupil be contracted and the conjunctiva insensible to touch there is generally no danger from this source. But remember, no single sign can be trusted. To prevent danger from the second source, the administrator should watch particularly the respiratory movements and observe the countenance, and I have no fault to find with those who look after the pulse too. Should respiration become weak, irregular or sighing, the countenance pallid, or the pulse irregular, rapid and feeble, the chloroform must be stopped at once. If during a prolonged operation signs of heart failure develop, anticipate danger by stopping the chloroform and completing the operation with ether.

Third Stage.—Notwithstanding all precautions, death sometimes occurs in this stage, and is then the result of direct paralysis of the centres of respiration and circulation, or both, by the chloroform. If, from heart failure, the face becomes very pale, the breathing weak, short and catching, the heart ceases to beat and the patient is in a state of syncope, (and all this sometimes with little or no warning,) stop the chloroform, lower the patient's head immediately, and if the heart does not at once resume its functions, commence artificial respiration. Hypodermic injections of digitalin and strychnia is the best accessory treatment.

If asphyxia threatens, the face becomes livid, the respiratory movements irregular and spasmodic, convulsive movements are seen and the breathing stops, while the heart continues to beat flutteringly. Here again chloroform must be stopped and artificial respiration immediately resorted to, care being taken to keep the patient's head low. Digitalis and strychnia are also very important adjuncts in completing the patient's recovery. I have seen a touch of a battery excite breathing after artificial respiration had been kept up for some seconds.

In any case of imminent danger, whether the heart or lungs be at fault, the patient's head being immediately lowered, artificial respiration should at once be commenced. Additional aids, such as those already mentioned, should also be practiced. It seems to me however, that the majority of deaths that occur in this stage are attributable to the combined effects of the chloroform on both the circulatory and respiratory centres, and not to either one separately, because the depressed condition of the circulation or respiration caused by the chloroform each aggravate the other on account of their mutual dependence upon each other.

Suppose the operation over. There is still a dangerous period of returning consciousness, during which the reflex centres are recovering their normal condition, and the connection between the heart and the cardiac centre is being re-established. If death occurs now it will be from syncope, and is most likely caused by impressions sent by the now distressed heart along the depressor filament of the vagus to the vaso-constrictor centre inhibiting its action and causing it to release its hold on all the vascular areas.

This is a much more dangerous form of syncope than that which occurs in the first stage, because by this time the heart is weakened by the action of the chloroform and its own intrinsic ganglia, and when it does occur death is almost certain to ensue.

The methods for the treatment of syncope before indicated must, of course, be assiduously employed.

Before leaving the subject of danger I wish to refer to the classes of cases in which death ensues in one, two, three or more days after the operation.

I have seen two cases, one in particular where the patient appeared to be in good condition after the operation and everything indicated ultimate success, but the pulse became gradually weaker, more irregular and rapid, in spite of all treatment, until death occurred at the end of thirty-six hours. Is death to be charged to chloroform? Yes.

One very important quality of the heart is elasticity, by means of which it is enabled to dilate when occasion requires and again resume its normal size when the emergency is passed. Now, a constant result of the administration of chloroform is dilatation of the heart, and it is clear that if its elasticity be impaired by any cause whatever, as by fatty degeneration, it may not be able to recover itself after the dilatation caused by the chloroform, and is consequently unable to sustain life long, although the patient may live through the operation.

If this be true, it follows that a fatty heart or a weak dilated one is a contra-indication to the use of chloroform; the Hyderabad Commission to the contrary. But here a great clinical difficulty meets us, that is the almost impossibility of recognizing this condition of the heart beforehand.

I now come to the second heading, "Administration of Chloroform."

Preparation of the Patient.—It is a well-known fact that chloroform is best administered on an empty stomach. No solid food should therefore be allowed for five or six hours before the operation, but a cup of soup or broth may be given with advantage two or three hours before. If a weak heart be suspected, strychnia and digitalis should be given for a couple of days before the operation. This treatment was first suggested by Professor Wood, of Philadelphia. The strychnia antidotes the chloroform and the digitalis tones up the heart. Other eminent authorities recommend alcohol before administering chloroform. Alcohol is not unlike chloroform in its physiological action, and the use of it is held to lessen the quantity of chloroform required. It is certainly of value in the case of habitual drunkards.

Suppose the patient now on the table. Don't commence the chloroform until everything and everybody is ready for the operation. If there is any waiting to be done let the operator be the one to do it. See that there are no false teeth in the mouth, nothing tight about the neck, chest or abdomen, don't allow two or three pillows, which is the usual request, place the head on a level with the trunk, or lower; this guards against syncope.

The patient may lie on the back or side, I prefer the side. This position allows the saliva and mucous to run out of the mouth instead of down the throat, and prevents the tongue from falling back. When the patient is under the influence of the anæsthetic he can be placed in any position the surgeon requires.

The slight struggling, which is sometimes seen, is no indication to stop the chloroform, some of the assistants can control the patient's movements. Vomiting is sometimes troublesome at this period. It is a reflex action, and the best cure for it is to push the chloroform until the vomiting centre is paralyzed. If it does occur, see that all solid particles are cleaned from the mouth and nostrils, and satisfy yourself that none has found its way into the trachea. Vomiting, however, often gives the most trouble after the operation, and I know of nothing that can be relied on to relieve this very distressing symptom. If an opportunity offers during a prolonged operation I would allow the patient to approach consciousness, this tests his powers of reviving and rests the heart.

The last point I will touch upon is in relation to the apparatus used in the administration, and I will at once state my preference for a Junker's Inhaler. This instrument is so arranged as to regulate the amount of chloroform taken at all times, it assures the admission of plenty of air and requires very little chloroform,

it is a simple instrument, and would be safe in the hands of the most inexperienced; but any apparatus is dangerous if it leads the operator to think that by using it he may relax his personal attention to the patient.

In conclusion I would say that I consider every one who administers chloroform should make himself aware of its dangers and should bear in mind the indications which announce these dangers. Every administration of chloroform is in itself a serious procedure and should only be undertaken with a feeling of responsibility, and with the consciousness that the life of the patient is in the hands of the administrator, and should occupy his constant and undivided attention.

An experienced and observant person will instinctively gather from numerous indications the approach of danger, and in the hands of such a person, the risks incident to the use of chloroform will be reduced to a minimum, but I do not believe that the danger factor can be wholly eliminated.—*Montreal Medical Journal.*

THE CUTANEOUS CICATRICES OF SYPHILIS.

Dr. Hyde, of Chicago, in speaking of "The Cutaneous Cicatrices of Syphilis" in the *Journal of Cutaneous and Genito-Urinary Diseases*, for March, 1893, states that from a diagnostic point of view, the value of the recognition of cicatures upon the body surface can readily be appreciated. The evidence thus furnished as to a prior surgical or accidental traumatism, or a previously active tuberculosis, zoster, or other cutaneous malady, may be both instructive and portentous.

This is more strikingly true of the cicatrices which are due to a disease which has had not merely a significant past, but may also have a formidable future. Such a disease is syphilis, whose persistent marking of the bodily surface may be of prime importance in determining the exact character of an epileptiform seizure, a pulmonary hemorrhage, a sudden hemiplegia, or an insidious albuminuria.

All properly trained physicians are more or less familiar with the typical cutaneous cicatrices produced by the degenerations and ulcerations of syphilis. They have no great difficulty in recognizing by inspection their cyclical outlines, their usually exact definition, their slight depression below the general level of the unaffected tissue about them, their generally superficial location, their freedom from deep attachments, their hue varying from the deepest chocolate to the dead whiteness of other ancient scars, and their smooth, even at times, lustrous surface. Usually, also, it is not very difficult to recognize the combinations formed after multiplication, and what may be termed coalescence of these typical cicatrices, producing thus outlines suggestive of the figure of "8," the letter "S," the horse-shoe, the kidney, and that arrangement of smaller, about arcs of the larger size similar to the devices of the jeweller whose gems are set about a brooch. It is rather with a view to recognizing the modifications of these type-scars, as they occur in different regions of the body that the present study has been attempted.

The cicatrices of syphilis on the scalp are usually obscure on casual inspection, by reason of the piliary growth with which they are surrounded and which must be removed in order to ensure careful observation. They may be loosely arranged in two groups, the one including the relatively large scars, the other those of smaller size; the former usually single and rarely more than double; the latter often but not necessarily multiple.

The single large scalp cicatrices of syphilis are rare and commonly occupy the greater part of the surface above the calvarium with the center approximately near the vertex. They betray the classical features mentioned above in their circular and oval outline, their superficial character, and their slight depression below the general level of the scalp. Very rarely indeed, however, are they to any degree pigmented, their color, when they are at all colored, being of the deep red empurpled hue of a more or less recent hæmatostasis. As a rule, after even a few weeks of healing, they are of a dirty

whitish or grayish hue. They are usually destitute of hairs save that here and there a single filament or a scanty wisp projects from the smooth or scaling plane of the atrophic disk. The greater part or but a small portion of these platter or palm-sized scars may be composite, the elementary contained disk being plainly of the order of the larger and containing circle, viz., a small coin-sized or finger-nail-sized depression within a depression, defined, rounded, and having either a smooth central area or one that is of the sort described above as scaling. This well-known condition in syphilitic scars, suggests the flaking of the thin scale of mica as that material appears in some articles of manufacture.

The smaller cicatrices of syphilis upon the scalp may be single, but are usually multiple, rarely exceeding six to ten in number. They vary in size from a split pea to a finger-nail, and are probably in numercial proportion to the lesions just described as the deep pustulo-crustaceous lesions of ecthymatous grade from which they generally take their origin, stand to the rarer gummata of the scalp. On account of the fact that they are usually hidden from the eye of the observer by long hairs of the scalp and are thus much less readily scrutinized than the large scars already described; the attention of the physician is rarely attracted to them after cicatrization is completed.

The syphilitic cicatrices of the face may be considered in three categories: First, the larger, few or single and asymmetrical; second, those which are small, few, and also, as a rule, asymmetrical; third, those which are numerous, small and symmetrical. These are named early in the order of frequency of occurrence.

In the first and second classes may be included the scars fairly classical as to type, occupying one side of the brow, near the scalp; those of exceedingly irregular outline with jagged edges found on one side of the root of the nose; and those occasionally seen on one cheek, the temple and just below the ear. The third group includes an interesting and significant class of lesions, usually originating in a copious crop of resolving or ulcerating tubercles.

Here the skin of the entire face may be symmetrically involved, or, what is more often noted, the upper segment only. The scars are numerous, flattened, closely set, defined, and very superficial, being remarkably smoothed away a few months after repair has been completed.

Upon the several regions of the neck, the trunk, and the hips, typical cicatrices due to syphilis occur in nearly the following order as to location: Above and below the clavicles, near the acromial extremity, over the scapular regions and the sternum, and upon the inferior segment of the abdomen and the lumbar region. They are more rarely seen in the axillæ about the iliac crests, and in the ano-genital region. In that last named, scars are more often due to venereal lesions of non-syphilitic origin, and the same may be said of the large majority of scars implicating the groins.

It is now well known that in both sexes and in the enormous mass of patients, chancre of the ano-genital region, precisely as in the case of extra-genital chancres, leaves no scars after healing. The cicatrices which are in rare instances left as sequelæ of these scleroses, result usually from irritative or traumatic accidents. Glancing at the upper and lower extremities together, we find a decided predominance of scars in the lower, due to the continued observance of the erect posture for hours at a time; a marked tendency to spare the hands and feet as distinguished from the arms, fore-arms, thighs and legs; a greater tendency to the clustering of scars about the elbows than about the knees, due to the effects of pressure in the trades; a preponderance of lesions upon the leg, as contrasted with the the thigh; an equal participation of arm and fore-arm in the ravages of the disease; a larger number of lesions upon the anterior as distinguished from the posterior faces of the legs, and the external as distinguished from the internal faces of the arms. The rarity of syphilitic scars upon the palms, soles, fingers, and toes, even though, as is not rare, the neighboring wrists and inner aspects of the ankles be involved, is a conspicuous fact. Syphilitic scars of the hands and feet are rarely symmetrical, affect the hands more often than the feet, and are found as a rule more distinctly outlined upon the dorsum of the hand thence spreading over the hypothenar eminence, rather than in the center of the palmar area.

Every practitioner is at times confronted with the question whether scars of the lower extremities, especially those spread over the anterior faces of the legs, are of syphilitic origin, or due to the common forms of engorgement and ulceration, not rarely associated with an obstinate eczema, indirectly caused by varicose veins of the part. In cases it is really difficult to decide between the two, but usually one may, on close inspection, discover finger-nail-sized circular and superficial, or even larger scars of characteristic syphilitic appearance, at one point or other of the large area distorted with cicatrization and discolored with pigment. The larger, very formidable, irregular, and deeply and extensively pigmented patches are usually not syphilitic, but due to the vascular mischief. The existence of ribbed, corded, seamed, or puckered patches, with remnants of varices in the neighborhood, is always significant of the latter.

In most of the doubtful cases the key to the diagnosis is to be sought not so much in the pigment that actually is present, as in that which has been. In a male subject of average weight and size, a wholly decolorized syphilitic scar of the leg, the decolorization process being just completed, points backward to an infection from four to eight years before, and a healing of the precedent ulcer between two and four years previously. It is probable, though not certain, that the decolorization is completed somewhat sooner in persons of a blonde type, and in women, the latter fact due to the less demand made upon their sex in the observance of the erect posture. This slow inevitable, but steadily progressive clearing up of the color, is characteristic of the syphilitic leg, while the steady continuance, for long periods of time, of the vascular disturbance which lies at the root of the eczemato-varicose extremity, produces the final picture of deep inky-black or chocolate-tinted pigmentation, spreading over half or more of the limb, and presenting, after years of trouble, no such amelioration of symptoms as in the infectious disease.

Signs of Shock.

Dr. Kottman, of Berlin, says that the most important signs of shock are weakness of the heart, faint respiration, skin pale and covered with cold sweat, face drawn out, sunken eyes, and livid lips; consciousness remains; sensibility reduced. Shock appears when certain very sensitive organs, as testicles, bones, or bowels have been subjected to contusion or other serious injury. Shock may occur from hemorrhage, and is then associated with functional changes in the body of which there are no post-mortem evidences. Two theories are advanced: the first defines shock as a reflex paralysis of the heart and vessels, caused by the trauma; according to the second, the injury causes, reflexly, exhaustion of the medulla oblongata and the spinal cord, and, as the nerve centres are affected, there is debility of heart and respiration. The fever which accompanies shock is, according to Dr. Kottman, the consequence of trauma. The substances causing the fever are here chemical and not bacterial, are freed from normal tissue matter by the injury, and include hemoglobin, fibrin ferment, and similar elements. He objects to confounding shock with debility due to hemorrhage. In the latter there is rapid pulse, quick, deep panting respiration. In shock the patient presents the evidences of cerebral irritation, noises in the ears, affected vision, palpitation, yawning, and even convulsions. In severe cases of shock the usual remedies—alcohol, ether, caffeine and camphor—may be used without relief. The similarity in the appearances resulting from hemorrhage and from shock induced Kottman to use salt-water transfusion in four cases with good results. By the neuro-pathological theory the explanation is that the effect of the salt solution is to stimulate the centres with which it comes in contact, and with increased arterial pressure the central nervous system would receive more blood and recuperate more quickly. If the hemo-pathological theory is accepted, the explanation is even more simple: the salt-water would fill the empty heart and vessels, and the hydraulic requirements would be fulfilled while the blood in the distended abdominal vessels was being restored to the circulation. Patients suffering from shock often require severe operations, especially the amputation of members. Experience shows that chloroform anæsthesia in these cases is attended with unusual danger; the danger is less with ether.—*Amer. Jour. Med. Soc.*

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF OBSTETRICS for April. Dr. Franklin H. Martin contributes an article on

Vaginal Ligation of a Portion of the Broad Ligaments for Uterine Tumors or Hemorrhage.

The operation proposed consists in "the ligation of more or less of the broad ligament with its vessels and nerves, the extent of the ligation depending on the result sought, from a simple ligation of the base of the ligament including the uterine arteries and branches of both sides without opening the peritoneum, to a complete ligation of the ligament of one side, including both uterine and ovarian arteries, with partial ligation of the opposite ligament without opening the peritoneal cavity, if possible, but by doing so if necessary." "The results sought in the operation are, first, checking of hemorrhages of the uterus by cutting off blood channels; and second, changing the nutrition of the uterus by interfering with its nerve supply, with the idea of modifying neoplasms which depend upon that organ for their nourishment and growth." The operation is performed with the patient in the lithotomy position, an incision being made in each lateral vaginal fornix, and a ligature applied by means of a curved needle with the finger as a guide. The conditions for which the author proposes applying the procedure are: "1. Acute hemorrhage of the cervix from all acute or chronic causes, which cannot be readily controlled by milder methods, as [*a*], rupture of the cervix in child-birth, by operation or by any other cause; [*b*], cancer of the cervix. 2. Hemorrhage from the body of the uterus as a result of abnormal growths: [*a*], fibromyomata; [*b*], sarcoma; [*c*], carcinomata; [*d*], intractable hemorrhagic endometritis. 3. For the purpose of changing the nutrition of myofibromatous tumors so that they will shrink in size, and, when of small dimensions, disappear altogether." The paper includes the report of two cases in which the operation was performed successfully, and is illustrated by cuts showing the blood supply of the uterus, and also the various steps of the operation.

Dr. Egbert H. Grandin, in a paper entitled "The Relative value of certain Obstetrical Operations," discusses the positions of Embryotomy, Cæsarean Section and Symphysiotomy in modern obstetrics, and urges the necessity of a thorough knowledge of the capacity and shape of the pelvis of every pregnant woman in order that the attendant may be prepared to render operative aid if such be demanded.

Dr. J. Clifton Edgar contributes an article on

Embryotomy,

in which the statistics of the operation are thoroughly discussed. He divides the subject into the two heads—embryotomy on the dead, and on the living fœtus. His conclusions are:

A. Embryotomy upon the dead fœtus. Embryotomy upon the dead fœtus is demanded when, the *absolute* indication for Cæsarean section being absent, the extraction of the fœtus undiminished in size would increase the dangers to the mother.

[*a*], This indication includes moderate degrees of pelvic contraction, malpresentations and positions, deformities of the fœtus, and slight obstruction in the soft parts.

[*b*], In markedly contracted pelves, with a transverse diameter at the inlet of at least three inches and a conjugata vera little under two and five-eighths inches, embryotomy, in combination, if need be, with pubiotomy (embryo-pubiotomy), other things being equal, will be indicated.

[*c*], In instances where the conjugata vera is much under two and five-eighths inches, when labor is obstructed by fixed pelvic tumor, extensive exostosis, advanced cancer of the cervix, celiotomy is to be preferred whether the fœtus be dead or alive.

[*d*], Where the mother's condition demands rapid delivery, and the absolute indication for Cæsarean section is absent.

B. Embryotomy upon the living fœtus. [*a*], Embryotomy upon the living fœtus is indicated during labor whenever the *relative indication* exists and the physical signs indicate that the life of the fœtus is practically lost.

[*b*], In certain rare instances, also, when the condition of the mother is such (temperature, pulse, dangerous thinning of the lower uterine segment), whether from repeated unsuccessful attempts at delivery or prolonged labor, as to render embryotomy by far the safer operation.

[*c*], In obstructed labor due to monstrosities.

The article is illustrated by cuts of various forms of cranioclasts.

Dr. Robert A. Murray in an article on

The Limitations of Cæsarean Section

reviews the Porro, improved Cæsarean and Symphysiotomy operations, giving the statistics of each. In regard to symphysiotomy he says, "It must, however, be exceptional that a child of seven and a half pounds can be delivered in a pelvis of even two and three-eighths alive by pubiotomy, and he is inclined to believe that in the hands of American operators it will find its best scope in moderate deformities of the justo-minor type of three and a half to four inches conjugate, or in bad presentations where the child's head is large, and thus save from craniotomy, more especially as the forceps may be tried first." Craniotomy, he thinks, will be confined to cases where the fœtus is dead, though it should also be performed in certain cases where the child is alive, as in hydrocephalus, also in the case of locked twins that have been mismanaged; but the child should always if possible, be given a chance. His conclusions are:

1. Cæsarean section should be done always

where the conjugata vera is below two and three-quarter inches.

2. It should be done in the Roberts or Nagele pelvis with marked deformity, or where there is fixation of one or both sacro-iliac synchondroses from diseases—cases in which pubiotomy would be ineffective.

3. It is the best operation with diameters even larger than two and three-quarter inches, when the child's head is large and could not possibly pass a living child if pubiotomy were done.

4. Where tumors or exostoses are present the Cæsarean section or the Porro operation is the best.

5. In cases of cancer of the cervix it should be chosen rather than pubiotomy, and should be done before labor sets in, so that no sepsis result.

6. The size of the child's head, in moderate contractions at the superior strait, will oftentimes be the determining factor as to whether an elective Cæsarean section or a pubiotomy will be the best operation.

Dr. Henry C. Coe discusses

Cancer of the Cervix Uteri Complicating Pregnancy,

reporting a case. The author believes that, under some circumstances, incipient epithelioma actually favors conception in those who have been long sterile, by determining an unusual flow of blood to the uterus and thus increasing the receptivity of the endometrium. Pregnancy is not likely to be interrupted unless the disease extends as high as the os internum; though on this point there is some difference of opinion. When the disease is confined to one lip, spontaneous delivery is the rule, the prognosis for both mother and child being better when the posterior lip is effected. When the entire *portio* is diseased spontaneous delivery is less common, and there is always immediate risk of deep multiple lacerations of the cervix, or rupture of the uterus, and subsequent danger of hemorrhage and septicæmia.

In regard to the diagnosis, it is important to note that the significance of the irregular hemorrhages during pregnancy may be misinterpreted, being referred to placenta previa, erosion of the cervix, etc., rather than to malignant disease. The absence of a foul discharge, or impairment of the general health, is, of course, no criterion.

As to treatment, if the patient is seen for the first time, when less than three months pregnant, he would not hesitate, in the interests of the mother, to either amputate the cervix at once or, which he thinks is the better plan, to first induce abortion and subsequently to operate. After the third month, with the patient under close observation, and treatment with astringents and antiseptics, she ought to be brought safely through pregnancy unless the disease extends rapidly and involves the peri-uterine tissues. If it does there is no object in operating, since the the mother will not be cured and the child will be sacrificed. The cautious use of the sharp spoon and the thermo-cautery around, not in, the cervical canal may serve to arrest its progress until term. The author believes that if there is cicatricial stenosis, the mother runs almost as much risk from premature delivery as from labor at term. If the disease is limited, dilatation of the os may proceed normally, patience and non-interference being required. If there is a complete cicatricial ring it is better to use Barnes' bags at the outset rather than allow the patient to become exhausted by ineffectual efforts. Multiple incisions into the cervix can be made if necessary, though there is some risk if there is much friable vascular tissue and the peri-uterine tissues or vesico-vaginal septum are infiltrated. Statistics favor the application of forceps rather than version. Craniotomy does not seem to have been successful. Cæsarean section should be performed two or three weeks before term, as in this way exhaustion and septic infection of the mother and the premature death of the child are avoided. No time should be lost in operating on the uterus after the puerperium. In the case reported by the author, the pregnancy was allowed to go to term. Subsequently the author performed a vaginal hysterectomy with success.

Dr. William Keiller contributes a scholarly article on

Axis-traction Forceps

showing clearly the mechanical principles that underlie their use. The author champions especially the form of traction forceps devised by Dr. Milne Murray, of Edinburgh, which is essentially the Tarnier rods applied to the long Simpson forceps. The author states that the forceps are especially useful in guarding against tears of the pelvic floor, as by their traction principle they compel the head to follow the axis of the vagina and cause it to be born in a position of flexion, instead of extension taking place at the vaginal outlet and causing lacerations. The instrument is equally valuable in the high applications as in the low. The paper is illustrated by diagrams and cuts of instruments.

Dr. Mary A. Dixon Jones, in a paper on "Colpo-hysterectomy for Malignant Disease," reports five cases in which there was no return of the disease after its removal, although in some cases several years have elapsed. These few cases, she says, "proved beyond a doubt that, by a timely operation, malignant disease may be eradicated from the system." The literature and statistics of the subject are reviewed in the paper, which will be continued in the next issue.

Dr. Albert S. Ashmead, in an interesting article entitled "Kangawiana," describes the obstetric practice and procedures among the Japanese, as established by the family of Kangawa, the hereditary obstetricians of Japan.

Dr. William H. Wathen contributes a paper on "Umbilical and Ventral Hernia," which was read before the Southern Surgical and Gynecological Association at Louisville, November, 1892, and which has appeared in abstract in THE MEDICAL AND SURGICAL REPORTER for Dec. 3rd, 1892, page 890.

Dr. Carl Beck reports a case of "Ectopic Pregnancy Twice in the same Patient, the

Second Time Complicated by Intestinal Obstruction." The patient recovered from the second operation.

Dr. Thomas C. Smith reports a "Sarcoma of the Uterus previous to Puberty." Such an occurrence is extremely rare and the diagnosis is proved by microscopical examination of the specimen by an expert.

Dr. I. S. Stone contributes a "Note on Drainage after Laparotomy." He says: "I have not lost a patient after laparotomy when drainage was not used, but the case reported, and two others which gave some anxiety, have caused me to urge more care in these cases where we do not suspect danger, and to insist upon the use of drainage in every case where any fluid is found in the appendages. I have not seen any bad results from the use of the drainage tube, although it does not always answer the desired purpose, and I have frequently used the gauze drain with signal advantage.

[In the case reported it was necessary to re-open the abdomen for the purpose of drainage.—ED.]

Dr. Howard A. Kelly advocates the use of glass trocars for tapping large ovarian cysts. The instrument, which is figured in the communication, differs from that in ordinary use only in being made of glass, on which account Dr. Kelly thinks it can be more easily kept clean.

This issue closes with a memoral notice of the late Dr. Charles Pratt Strong, of Boston.

THE KANSAS CITY MEDICAL INDEX.

Dr. J. C. McClintock, in a clinical lecture, reports "A Secondary Laparotomy" which was performed for the release of adhesions: A case of "Talipes" associated with deformity of both hands. Three of the fingers were without a third phalanx, while the thumb on the right hand had three phalanges and two fingers had small growths projecting from the phalangeal articulation. The talipes was treated by the simple application of a plaster-of-Paris splint, the foot being semi-flexed and rotated outward while the plaster was wet and so held until the plaster had set: The third case reported was one in which a girl of six months, had swallowed a jack-stone six weeks previously. The foreign body was detected in the œsophagus by the finger and removed: The fourth case was one of uterine polypi: The fifth case was one of

Perforation of the Abdominal Walls by a Cow's Horn.

An examination showed that the horn had entered two inches below and to the left of the umbilicus, and had emerged two inches above the right anterior superior spinous process of the ilium, tearing up an irregular triangular shaped flap, with the apex of the triangle almost down to the middle of Poupart's ligament. The muscles and peritoneum were perforated below the umbilicus, the perforation extending outward to the right, making a tear 2½ inches in length.

Warm water was poured over the wound, washing the omentum, 8 inches of which protruded from the peritoneal tear. The patient was suffering profound shock, but rallied when the flaps were covered with towels wrung out of hot water, The peritoneum, muscles and fascia were closed with a continuous silk suture cut short. Then the rough edges of the superficial structures were brought together with interruptured sutures, a piece of gauze inserted into the lower corner for drainage and a bandage applied. The patient recovered.

Dr. J. S. Poyner describes the "Removal of the Secundines with the Capiat." After reviewing the difficulties usually encountered in cleaning out a uterus after abortion, the author proceeds to describe an instrument of his own invention which he has named the capiat and which is designed to remove the debris from the uterus. The instrument consists of a tube nine or ten inches long, through which extends a rod having a set of six springs fitted at its distal end, so arranged as to protrude when the tube is withdrawn. When the rod is rotated one-third of a turn, the springs are distributed around in equal spaces, forming a closed basket, which will have enclosed any substance which may have been in the cavity of the uterus.

Dr. James H. Etheridge presents a "Report of Laparotomies Performed" which has already been noticed in the MEDICAL AND SURGICAL REPORTER for March 25th, 1893, page 473.

Dr. H. C. Dalton reports

Some Cases of Laparotomy for Stab Wounds.

The cases are:

I. Stab wound of the gall-bladder and stomach. Laparotomy, recovery.

II. Stab wound of the liver. Laparotomy, recovery.

III. Stab wound of the liver. Laparotomy, death. In these two cases the wounds in the liver were closed with heavy catgut sutures.

IV. Stab wounds of liver and stomach Laparotomy, recovery.

The author states that he has been gradually coming to the conclusion that surgeons irrigate too much in laparotomies for recent injuries. He believes that even when the gut, bladder or other viscera is found cut or shot, and blood and a small quantity of urine or fæces extravasated, better results would be gotten by trusting to the sponge. Of course if a large amount of fæces or urine be found, irrigation would be imperatively demanded. He thinks that septic material is often forced among the intestinal coils by the irrigation, thus increasing the danger. He is also quite skeptical as to the good results of drainage in recent abdominal injuries, and thinks it should never be used save when sepsis is suspected or when the intestines have been handled for a considerable length of time. A safe rule is that the necessity which calls for irrigation calls also for drainage.

Mr. Jonathan Hutchinson, F. R. C. S. London, Eng., contributes a short sketch on the

Treatment of Gonorrhœa.

He always uses abortive measures and

mostly succeeds. He advises, first, an injection of solution of chloride of zinc, two grains to the ounce; next, sandal-wood oil capsules; and lastly, a purgative night dose, with bromide of potassium. The injection is used three times a day, the capsules (ten or twenty minims) taken three times a day. The ingredients of the night dose are three drachms of Epsom salts and a half drachm of bromide of potassium. He believes it is the action of the last named in preventing congestion of the parts that makes the abortive measures safe. If the case is very acute he sometimes prescribes tartar emetic, or tincture of aconite, but it is seldom that these are necessary. If the patient is well purged, there is no risk in the abortive treatment from the day he comes under treatment. He would as soon think of delaying to use local measures in gonorrhœa, as he should in purulent ophthalmia.

Dr. Emory Lanphear describes

A New and Rapid Method for Hysterectomy.

After antiseptic preparation of the patient, an incision is made through the abdominal wall close to the middle line, four inches or more in length. The ovary and tube of one side are caught and pulled into the opening, and a clamp applied to their outer side; but as close to the uterine body as possible; a heavy catgut ligature is passed through the broad ligament, tied, and a cut made between the ligature and the clamp; this suturing may be continued downward into the pelvis as far as convenient. The other side is then treated in the same manner, when the uterus, with its attached tubes and ovaries, may readily be brought up into the opening. The fundus is now tilted backward, a cut made transversely across the uterus, through the peritoneum, and separation of bladder from womb accomplished methodically and completely. This line of incision should be made just behind the vesico-uterine fold, which is easily recognized by touch; the dissection is done partly by fingers and partly with some blunt instrument, (I prefer the end of my blunt-pointed curved scissors used closed) the bladder being pressed away little by little, below and in front. When the region of the os tincæ is reached one finger is slipped into the vagina, the exact location determined, and the scissors pushed through the mucous membrane; this opening is extended across the anterior surface of the cervix as in the initial step of vaginal hysterectomy, save that the cut is made from above instead of below. The uterus now being pulled strongly forward a similar separation of uterus from rectum is made, but not nearly so much care is required as the distance is short and perforation of the rectum not easy.

When the opening through the cul-de-sac of Douglas is complete the sides may be ligated and the uterus cut away. As thus performed supravaginal hysterectomy is scarcely more serious than vaginal, the cut through the abdominal wall adding but an insignificant amount of danger to the operation. In cases where some special reason exists for so doing the peritoneum on the posterior wall of the bladder may be united to that of the anterior wall of the rectum by a few catgut stitches.

Dr. A. H. Cordier considers the subject of "Puerperal Sepsis," reporting a case where laparotomy was performed without success.

THE CANADIAN PRACTITIONER

for March is wholly taken up with the study of Cholera in its different bearings.

Dr. George M. Sternberg contributes an article on the

Bacteriology of Cholera and Methods of Disinfection.

He says, the spirillum grows readily in the presence of oxygen, and also in the absence of oxygen, as it must do to thrive in the intestines. It does not form spores and is consequently easily destroyed. Milk is a very favorable medium for its growth, but it will not grow in acid media. There is sufficient pabulum for its growth in ordinary river or well water, but in water which is rich in organic pabulum, and consequently contains nnmerous other common organisms, it dies out as these take the precedence; so it would apparently multiply more rapidly in water not containing a large amount of organic material than it would in sewage. Koch found in his earliest investigation that this spirillum grows readily on moist linen, or the soiled clothing of patients. Ten minutes exposure to a temperature of 60° C.=140° F.—may be relied on for the destruction of the spirillum. Another very important point is that they are quickly destroyed by desiccation. As a means of disinfection he recommends steam at 100° C., carbolic acid, chloride of lime and æration. An agent which is very valuable and very important is recently slacked lime.

Dr. Albert L. Gihon considers the "Hygiene of Cholera," and Dr. A. C. Abbott the "Prophylactic Measures against Asiatic Cholera," describing the measures that should be taken during the prevalence of an epidemic.

Dr. Henry Hartshone, in a paper on "Cholera and its Migrations," describes the course taken by the various epidemics.

Dr. Roberts Bartholow discusses

The Treatment of Cholera.

Of all the remedies proposed for the arrest of the diarrhœa not one has done so much good, in the writer's experience, as sulphuric acid. It is usual, and generally best, to combine some opium with it according to the following formulæ:

℞ Acid sulphuric aromat.....5v.
Tinct. opii deodorat.....5iij.
M. Sig. From ten to twenty drops every hour or two in sufficient water.

℞ Acid sulphuric dil.....5ii.
Tinct. opii camph.....5xiij.
M. Sig. A teaspoonful every half hour in water.

The remedies of which the most has been expected were salol and creolin, but the practical outcome has not been so fortunate as the promoters hoped for and predicted. From his observations of the effects of naph-

thalin in the various forms of diarrhœa, he is inclined to believe that this remedy promises well. As under ordinary circumstances it affects the whole intestinal canal, deorderizes the stools and restrains the peristaltic movements, it should under the different conditions of a true cholera attack accomplish similar results. Naphthalin may be combined with bismuth and carbolic acid, and opium may enter into the combination, if necessary. The use of calomel is also reviewed by the writer. He then proceeds to consider the subject of Enteroclysis, or irrigation of the intestine with a solution of tannic acid, giving the opinions of various observers. His opinion is that it is not of much value, since "it is difficult to understand how irrigation of the large intestine can modify a morbid process going on in the small intestine, for nothing is more certain than that an injected fluid does not pass beyond the ileo-cæcal valve." The infusion of a saline solution into the veins and hypodermatoclysis, or the injection of a saline solution under the skin, are recommended for the treatment of the algid stage, with the advantage on the side of the intra-venous infusion. External heat should also be applied in the shape of hot bricks, hot baths, etc. For the muscular cramps he advocates the use of chloral hydrate combined with morphia and atropia. They should be given hypodermically; the chloral in ten grain doses by itself, and the morphia and atropia together, in the dose of from $\frac{1}{8}$ to $\frac{1}{4}$ grain of morphia and from $\frac{1}{120}$ to $\frac{1}{60}$ grain of atropia. The attempt to feed a cholera patient when the digestive tract is undergoing desquamation is worse than useless. Beef tea is only harmful. A little cold milk or wine-whey may be given as the state of the stomach will permit. Thirst is excessive and the indulgence in water drinking is likely to excite vomiting, but the advantages due to the free use of water more than counterbalance the injury from a renewal or increase of the vomiting. Carbonic acid water may agree better than simple water. As the renal functions are suspended, or nearly so, and, as during the typhoid stage the restoration of these functions are of the first importance, the free use of diluents may prove, in a high degree, useful.

The last article in the series is "A Clinical Study of Eleven Cases of Asiatic Cholera treated by Hypodermoclysis and Enteroclysis," by Dr. Judson Daland and has already been noticed in THE MEDICAL AND SURGICAL REPORTER for January 14th, 1893, page 74.

Under Clinical Notes, Dr. Charles B. Langford reports "A Case of Compound Fracture of the Skull followed by Suppuration." Dr. W. B. Thistle reports "A Case of Hystero-epilepsy in a Child of Three," and Dr. J. W. E. Brown presents the notes of a "Case of Aortic Aneurism."

SELECTED FORMULÆ.

Frosted Feet, Etc.

Dr. W. S. Cline sends the following prescription, which he says "is worth its weight in gold" (*Va. Med. Mo.*). It will relieve "frosted feet" as promptly as morphia will pain:

℞ Carbolic acid.....ʒj
Tinct. iodine.....ʒij.
Tannic Acid.....ʒj.
Simple ointment.....ʒiv.

M. Sig. Apply twice a day.

The following ointment is recommended by Prof. Keen in cases of erysipelas:

℞ Ungt. zinci oxidi.....ʒij.
Hydrarg. chlorid. mitis.....ʒij.

M. Ft. unguentum. Apply to parts.

Sulphur Iodide in Acne.

[HILLES—*Deut. Med. Woch.*]

OINTMENT.

℞ Sulphur iodide.....0.6 gm. (10 grs.)
Lanolin.....30.0 gms. (1 oz.)

Apply twice daily, after washing the parts with hot water.

To Remove Wax from the Ear.

Dr. A. P. Brubaker advises:

℞ Potassi carbonatis.....grs. xxx.
Glycerini.....fl. ʒiij.
Aquæ destillat.....fl. ʒiv.

M. Sig. To be injected into the ear.

For Erysipelas.

Take of:

℞ Icthyol.....4 dr.
Lanoline.....4 dr.

Make an ounce ointment, and apply to the affected part, then cover it with salicylic acid gauze.

—*Poplar Med. Monthly.*

Tubercular Abscesses.

Tubercular abscesses are recommended by Billroth to be treated as follows:

℞ Iodoform.....ʒij.
Glycerini.....ʒijss.

M. Sig. Inject into the abscess cavity after evacuating the pus.

Mucous Patches in the Mouth.

A certain amount of relief may be afforded by the frequent use of a gargle and mouth-wash, as follows (*Med. Bull.*):

℞ Acidi borici..... ʒij.
Glycerini..... ʒij.
Tr. myrrh..... ʒj.
Aq. rosæ..... q. s. ad ʒviij.

M.

Or,

℞ Sodii biborat..... ʒjss.
Sodii bicarb..... gr. xxx.
Thymol..... gr. iij.
Glycerini..... ʒj.
Aq. laurocerasi..... q. s. ad ʒiv.

M.

Local Anæsthesia.

For minor operations the following, used as a spray, is recommended :

℞ Mentholi.....part i.
Chloroformi.....part x.
Ætheris fort.....parts xv.
M. Ft. solut.

Dentifrices for Mercurial Stomatitis.

Dr. Leonte (*Spitalul*, No. 23, 1892), recommends as a dentifrice in mercurial stomatitis the following :

℞ Powdered salol, Boric acid } aa.....20 gms. (℥v.)
Saccharine, Menthol } aa..... 20 cgms. (grs. iij.)

Brush the teeth twice a day with this mixture upon a soft brush.

Treatment of Croup.

Prof. N. S. Davis says all the indications for treatment in croup, in the mild or superficial form of the disease, can be filled by the administration of :

℞ Syr. ipecac..... ℥ix.
Syr. scillae comp..... ℥iss.
Tinct. opii camph..... ℥ii.
M. Sig.—Half teaspoonful every three or four hours

—Indiana Medical Journal.

Intestinal Fluxes, etc.

According to Dr. J. Zach Taylor, (*Times and Register*) this dangerous disease, as well as its allied disorders of the bowels, will readily yield to the following formula which, after a trial of over twenty years, he regards as almost a specific.

℞ Pulv. Opii.
Pulv. Plumbi Acetat. aa..... gr. xxx.
Camphor gum.
Extract Capsicum Fld..... gtt. x.
Buchwood Creasote..... gtt. v.
Alcohol q. s. to dissolve camphor.
M. Ft. Pil. No. xxx.
Sig. One to six pills daily, according to urgency of case.

Cystitis.

Professor Bangs treats successfully, cases of cystitis, by washing out the bladder with a boro-salicylic solution and injecting twice daily one to three drachms of the following solution.

℞ Iodoformi..... ℥ij.
Glycerini, Mucil. Acaciæ..... āā. ℥fs.
Aquae ad..... ℥viii.

M, Rub up the iodoform with the mucilage, then add glycerine and water.
Sig. Use as above.

Ointment for Barber's Itch.

During the inflammatory stage the following should be applied :

℞ Ichthyol..... gr. xx.
Salicylic acid..... gr. x.
Oleate of mercury (10 per cent)... ℥ij.
Oil of lavender..... miij.
Lanoline..... ℥vj.
Mix.
This to be kept constantly applied to the affected parts.

—Chem. and Drug.

Tonic Laxative.

Dr. Clinton Cushing in his gynecological clinic makes frequent use of the following prescription :

℞ Ext. casc. sag ..... ℥j.
Ext. nucis vom.....
Ext. hyoscyam..... aa ℥j.
Ol. anisi..... gtt. xv.
M.
Sig. A small teaspoonful at bedtime.

—Occ. Med. Times.

For Bronchial Asthma.

℞ Potassii iodidi..... ℥ij.
Tincturae scillae..... ℥j.
Tincturae stramonii..... ℥ij.
Extracti glycyrrhizae liquidi..... ℥iij.
Spiritus etheris..... ℥j.
Aquae..... ad ℥viij.
M.
Sig. One tablespoonful in a teaspoonful of water every six hours.

—Ex.

For Irritable Cough.

℞ Acidi hydrocyanici diluti..... ℥iss.
Morphinae acetatis..... gr. iss.
Mucilaginis acaciae..... ℥j.
Syrupi pruni virginianae..... ℥iv.
Aquam..... ad ℥vj.
Misce et fiat mistura.
A teaspoonful to be sipped every four or six hours.

—The Practitioner.

Seborrhea of the Scalp.

Paschkis washes the scalp with an alkaline solution containing soap and bicarbonate of soda. As a lotion he uses :

℞ Resorcin..... ℥i.
Alcohol..... ℥v.
Castor oil..... ℥ss.

When the seborrhea has disappeared, he uses friction, with some tonic, such as:

℞ Sulphate of quinine..... gr. xv.
Alcohol..... ℥ii.
Eau de Cologne..... ℥i.
S. For external use.

—Semaine Med.

Pomade for Psoriasis of Scalp.

Besnier gives the following :

℞ Potash soap.....
Vaselin..... aa ℥v.
Ichthyol..... ℥ss.
Salicylic ac.....
Pyrogallic acid..... aa gr. xx.
M.
Sig. To be applied every day to the plaques of psoriasis. If much irritation is created, suspend the application temporarily.

—Ex.

Dilute Nitrohydrochloric Acid

Is best given along with a little hydrochloric acid, according to Dr. Lockhart Gillespie. In treating that form of headache which Dr. Lauder Brunton has shown to be relieved by the administration of acids—namely, when the pain is frontal and close above the frontal sinuses—the two acids in small quantity, added to a moderate dose of antipyrin or other analgesic, subdue the pain more rapidly than any of these drugs separately. *—Chem. and Drug.*

NATURAL AND ARTIFICIAL DRYNESS IN CHAMPAGNE.

Natural dryness and the smallest percentage of alcohol constitute the purest and most wholesome champagne, as compared with artificial and spirituous dryness, which admits of a higher percentage of sugar in the wine, while giving a dryer but false taste, as is the case with several of the so-called "brut" wines. By chemical analysis of Prof. R. Ogden Doremus, G. H. Mumm's Extra Dry contains, in a marked degree, less alcohol than other prominent brands, and he recommends it, not only for its purity, but as the most wholesome champagne. These properties and its remarkable quality and natural dryness have made it the most popular, as is evidenced by Custom House statistics of 1892, showing G. H. Mumm's Extra Dry imports to be 75,880 cases, being more than one-fifth of the entire importation and over 9,000 cases more than of any other brand.

FIRWEIN! The Ideal Expectorant

WHY?

1. IT CONTAINS all the essential ingredients to relieve Coughs.
2. IT IS COMPOSED of the Balsams associated with Phosphorus, Iodine and Bromine.
3. EXPERIENCE has verified the effectiveness of the combination.
4. IT CAN BE GIVEN IN ALL cases where Cod Liver Oil is prescribed.

DISEASES

where prescribed and found unsurpassed.

ACUTE AND CHRONIC BRONCHITIS

LARYNGITIS,

PNEUMONIA,

ASTHMA and

PULMONARY TUBERCULOSIS

DOSE: One or Two Teaspoonfuls before meals, or oftener, regulated by age or disease
FORMULÆ: Each fluid drachm contains Phosphorus 1-100 of a grain; Iodine, 1-6 of a grain; Bromine, 1-6 grain

Prepared only by **THE TILDEN CO.**

ORIGINAL ARTICLES.

MULTIPLE NEURITIS.

EDWIN L. MARECHAL, M. D., Mobile, Ala.

In 1864 Duménil, of Rouen, published the following case which was the first in which an autopsy verified the existence of paralysis, due to degeneration of the peripheral nerves without spinal lesion:

"A tailor, aged 61, after suffering from prickling in the toes for two weeks, was suddenly taken with weakness in the left arm and right leg, and a few days later by the same paresis in the left leg. Within five days he could not stand or walk. The paralyzed feet hung flaccid and were totally paralyzed; the thighs could be moved freely. Anæsthesia was found on the right sole and calf, and on the left foot and outer side of the leg. In the muscles of the hands and forearms considerable atrophy with paralysis, developed. Faradic contractibility in the paralyzed muscles was abolished. He complained of a painful numbness in the paralyzed limbs up to the knees, and involving the hands. No improvement; death in four and one-half months.

Autopsy: Spinal cord and nerve roots normal. The finer nerve branches in the legs and hands were degenerated, only a small number of nerve fibres being found. Single fibres showed no continuous myelin sheath, but this was segmented and granular. There was an increase of connective tissue, and many fat cells in the nerves."

Previous to the publication of this case, the existence of diseased conditions of the peripheral nerves had been suspected as furnishing a rational explanation of many motor, sensory and trophic disturbances, but there were no reliable observations confirming such suspicions. Graves, the eminent clinician, had said that "all writers upon nervous diseases devoted all their inquiries in search of functional changes to the cerebrum, cerebellum or spinal marrow, forgetting that the causes may be resident in the nervous cords themselves, or their extremities." Mangus Huss, Lancereaux and Duchenne had given accurate description of alcoholic nervous symptoms, misinterpreting, however, their true nature and ascribing them to central lesion. Duchenne recorded many cases which he termed "general subacute ascending spinal paralysis," characterized by sensory, motor and trophic disturbances. In his opinion these cases were due to a gradually ascending lesion in the spinal cord, and this was in accord with the consensus of professional opinion when Duménil's observations demonstrated the origin in a widespread inflammation of the peripheral nerves. Subsequently the investigations of Leyden, Eichorst, Joffroy, and Grainger Stewart in Europe, and Allen Starr and Hun in this country, confirmed the opinion of Duménil and established for peripheral neuritis a distinct nosological position upon which many motor, sensory and trophic troubles are frequently dependent. To Leyden, probably more than to any one else, we are indebted for its differentation from other conditions with which it had been confounded, for in investigating atrophic paralysis he found

that with the exception of the disease under consideration, they were all due to either degeneration of the anterior gray horns of the cord, or of the motor cranial nerve nuclei; while multiple neuritis was a disease due to degeneration of the peripheral nerves without involvment of the cord; a disease characterized by atrophic paralysis, associated with sensory symptoms, tenderness in the nerves, and generally terminating in recovery.

The lesions found in multiple neuritis have been closely studied by Eichorst, Leyden, Oppenheim and Strümpell, and occur with almost absolute uniformity in every case. They are those of degenerative inflammation, in fact, of "secondary degeneration" so ably elucidated by Waller. Early in the disease the nerve is swollen from infiltration of its substance by lymphoid cells. Sometimes its consistency is changed from breaking down of its histological elements. Later, as the result of cell proliferation and pressure within the sheath, the myelin becomes broken up into a granular *dèbris*, and the axis cylinder, the functional element of the nerve, undergoes a solution of continuity which unfits it for the performance of its functions—to conduct nerve impulses. But, even before this disintegration of the axis cylinder occurs, there may be complete paralysis, with loss of electrical irritability; since, as Gowers suggests, the myelin, from its liquid consistence, diffuses pressure equally upon each inter-nodal portion of the axis cylinder, and at the same time probably has an insulating action, on account of its diseased condition may render the nerve unequal to the task of transmitting nerve impulses. The active increase in quantity and swollen and homogeneous condition of the myelin, subsequently becoming split up into segments, together with the growth and fission of the nuclei and the pressure of the liquid protoplasm inside the sheath of Schwann, consequent upon the inflammatory process going on, causes at first an enlargement of the nerve, but later on, when disintegration of its tissue has advanced to its full limit, the granular *dèbris* which is formed becomes absorbed, leaving the sheath empty and collapsed. Hence, when the inflammation has been widespread, the nerves may present every variety of lesion, from simple inflammatory infiltration to complete destruction of the axis cylinders with empty and collapsed sheaths.

It is still an undecided question among pathologists as to whether the inflammation originates with greater frequency in the parenchyma or connective tissue, and while it is conceded by all that it may be interstital or parenchymatous, as circumstances may determine, we are assured that after the process has advanced to complete degeneration no distinctive differences can be observed in the lesions of either variety. The changes which I have detailed most frequently occur in the peripheral terminations of the nerves, but the nerve trunks may be involved at their distal extremities. As a rule, none of these lesions are found in the spinal nerve roots. The brain, in some instances, more especially those of alcoholic origin, presents evidences of meningeal inflammation.

Degeneration of the muscles proceeds *pari passu* with the nerve changes. Following the fatty degeneration new connective tissue takes the place of the proper muscle fibre. Starr says, "that when no regeneration takes place a mass of connective tissue replaces the muscle containing a few muscular elements."

The process of regeneration is necessarily a slow one, and time required for its completion is entirely dependent upon the extent of the degeneration that has occurred. Where this is slight it may be rapid, and cases are on record where complete recovery, with restoration of nerve integrity, has been observed at the end of the second month. Generally, however, it is a slow process, and most cases require from six months to two years before the functions of the diseased nerves are re-established. In the absence of positive experimental data upon which to base an opinion it is inferred that the process of regeneration is that which follows experimental degeneration.

The occurrences of multiple neuritis under such a contrariety of circumstances has suggested to observers the advisability of classification of cases in accordance with their apparent causation, and while such a classification is desirable it must be confessed that, as yet, our knowledge is too inexact to justify an arbitrary division of that character, for in many cases, notwithstanding the most careful investigation, the pathogenic element eludes our

search. Nevertheless, for convenience of description, I shall group cases in three classes, leaving out as of no practical importance to us the nervous symptoms which occur in *beriberi* and leprosy and which have been ascribed to neuritis.

1. Cases due to alcohol, lead, arsenic, etc.

2. Those cases which occur in the course of infectious diseases and which are presumed to owe their origin to the direct action of the specific element of these diseases upon the nervous system.

3. Cases due to cold, exposure, dampness and to agencies whose influence is as yet unascertained.

1. Observers in different parts of the world have confirmed the views first advanced by Jackson in 1822, that alcohol is by far the most prolific cause of multiple neuritis. Whether or not this is due to the direct toxic action of alcohol upon the nervous system is not known. It is especially frequent among the higher classes whose nervous system are highly developed and whose lives are inactive. An indolent life, with daily indulgence in whiskey or brandy, creates a liability to this special form or nervous disorder. Women suffer more frequently than men. Alcohol, as Starr suggests, appears to exert its toxic effect in men by the production of cerebral disturbances, while in women it expends its force in the causation of nerve degeneration. Gowers had eight cases of typical alcoholic neuritis in women and none in men. Alcoholic paralysis, although apparently sudden in its onset, is usually preceded by a history of gastric disturbance with a train of nervous phenomena consisting of insomnia, tremor and unsteadiness of gait. Sometimes the cases assume from the beginning the tabetic type inducing the condition to which Déjérine has given the name pseudo-tabes.

When an attack of multiple neuritis is sudden in its onset it is marked by decided febrile reaction, the temperature ranging from 103° to 104°. This may persist for several days, and has a disposition to subside spontaneously, with no tendency to return. The fever may, however, become continuous, the temperature not being so high, the pulse ranging from 90 to 100. A pulse continuously over 100, with a tendency to become irregular, indicates involvement of the pneumogastrics and is of omnious significance. The mind is generally undisturbed, but in some cases there is active delirium and in others the patient becomes the victim of delusions. One noticeable feature in these cases is the disposition patients exhibit to deceive their medical attendant, resorting to the silliest subterfuges and even boldly lying, to evade the watchful supervision of those around him.

The sensory symptoms are co-incident with the beginning of the disease, and persist during its whole course. Numbness, tingling and fornication usher in the attack, and the great discomfort which they induce is frequently what impels the patient to seek medical advice. Paræsthesia begins in the hands and feet, and extends to the elbows and knees. There may be burning, boring, tearing sensations, but they usually subside as the disease advances. Pain is a frequent accompaniment, and may be so severe as to require opium for its relief. It is usually moderate and not continuous. Indeed it is rarely as aggravating as the lightning pains of tabes dorsalis. Along the course of the affected nerves and in the muscles which they supply there is great tenderness, and this, in some cases, is so marked as to prevent the use of electricity for diagnostic purposes. Should the tenderness and pain be referred to the joints with coexistent œdema it may be difficult to differentiate it from acute articular rheumatism. There are hyperæsthesia and anæsthesia, that is to say, there may be localized spots of anæsthesia while the limbs are markedly hyperæsthetic. Tactile sense is frequently lost, and the transmission of pain and temperature may be delayed. Sometimes the muscle sense is so delayed as to induce incöordination and ataxia, thereby misleading the attendant as to the nature of the case. The disturbances of sensation in exceptional instances involve the whole extremities and even the trunk, but they are usually limited to the hands and feet. Lowenfeld has recorded a case in which facial tingling with anæsthesia occurred. The special senses are rarely affected, although in a few cases optic neuritis has occurred, and in some disturbances of hearing have been observed.

The paralysis so characteristic of the disease manifests itself in the beginning

by weakness, and a feeling of fatigue on exertion. This is rapid in its progress, two or three weeks only elapsing before the patient is helpless. The onset of the motor symptoms, however, may be less sudden, and there may not be entire loss of power of walking for several months. In some cases at the end of only a few days the limbs may be completely paralyzed. The distribution of the paralysis is not uniform for it may develop in muscles supplied by a single nerve and slowly invade those supplied by other nerves. It may invade the feet first and then progressively advance until all four limbs are affected. It is more marked in the extensors of the hands and flexors of the feet, producing wrist-drop and foot-drop. The muscles moving the knees and elbows are rarely affected. When the disease has become complete, total paralysis of all the muscles below the knees and elbows exists. Rarely the muscles of the arms, thighs, and trunk, become involved. Only in rare and fatal cases are the muscles of deglutition affected. Brazelius has published a case in which not only all the facial branches of the facial nerves were paralyzed, but also the muscles of the neck, of the trunk, and extremities, were paretic. All the muscles paralyzed are relaxed and flabby, and they may or may not lose their mechanical irritability. As a general rule the tendon reflexes are absent, although in exceptional instances they have been exaggerated. Sometimes there is simple diminution of electrical excitability, and a strong current is required to produce contractions. Often all faradic excitability is lost, and the muscles react only in response to a strong galvanic current. When the degeneration is complete, there is reaction of degeneration. Still, in a few cases, the normal reaction is found, the negative pole producing stronger contractions than the positive. Finally, atrophy and contraction of the muscles occur, leading to grave deformities.

An œdematous condition of the affected limbs sometimes occurs. The surface becomes smooth and shiny, the skin appearing as if stretched to its full extent over the underlying structures, the natural creases and lines being obliterated.

I. M., aged 23, a constant drinker, and, though not given to sprees, had not been careful as to the quantity or quality of whiskey drank. Had been exposed to cold and wet, but this could not have produced present illness, inasmuch as trouble did not follow early enough after exposure. In June, 1885, while returning home from a distance, he noticed, for the first time, a peculiar feeling under and about the great toe of the right foot, as if it were being lifted off. The same night the paræsthesia extended to the rest of the foot, and the next day sensation was similarly disturbed in the other foot. This travelled symetrically up the lower extremities until it reached the waist, shading off generally from half-way up the thighs. Two months after the beginning of the disturbance, the patient was conscious of steadily increasing loss of muscular power, and of atrophy. Until October, 1886, he was unable to be around. Since then he has been confined to the house, locomotion being accomplished with difficulty. During the time has suffered with muscular pain of increasing severity.

Condition when first seen March, 1887: His case has been pronounced locomotor ataxia, and such he believes it to be. Muscles of the thighs and legs atrophied and flabby. Extremities cold and clammy. Every motion of the lower extremities is accompanied with pain. Respiration rapid and abdominal. Tactile sense much impaired, that is, he is not able to designate within two to four inches of where an object is placed in contact with his body. Sometimes not conscious of contact at all. Temperature sense impaired. There is no sensibility to faradic current until half way up the thighs, and then only to a strong current. Galvanic current showed R. D., in the muscles of the lower extremities and to a slight degree in the extensors of the wrists and fingers. Pressure on the muscles of the lower extremities causes intense pain. There is a painful and annoying sensation about the scrotum "as if being torn away." Patella reflex exaggerated. Eyesight not as good as formerly, but the Argyl-Robertson pupil phenomenon is not present. Cöordination good. Is constantly in pain, and from broken rest is weak and emaciated. Locomotion is only accomplished with difficulty by grasping objects for support, or with the aid of attendants. Sexual desire gone. Diagnosis: Multiple neuritis. Recovery (Star-

kel, St. Louis *Courier of Medicine,* August, 1887).

II. A., book-keeper, aged——, had led an inactive life and was an habitual secret drinker, inbibing large quantities of liquor. Six months prior to present illness began to suffer with depraved appetite and other evidences of digestive disturbance. These increased and there supervened symptoms of delirium tremens with aggravating pain in the left arm and leg. At the expiration of five months he was forced from his condition to give up work. He became very moody and reticent. A few days after this the left arm and leg became paralyzed. There was great tenderness over the nerves. Wrist-drop and foot-drop marked. His speech became so affected that he could not speak so that he could be understood, every effort to do so resulting in a hissing sound, due to an involvement of the nerves governing the muscles of phonation in the degenerative process. The mind was much disturbed, and while his attention could be secured he soon lapsed into a condition of apathy. There was great restlessness, with picking at the bedclothes. He would sleep quietly for a few minutes, and this would be interrupted by delusions. The bowels were constipated. The bladder at first acted normally, but it became necessary toward the termination of the case to use the catheter. Deglutition was very difficult. The vital functions became more and more depressed and the pulse become imperceptible at the wrist. The temperature, which at first was 101°, now became subnormal. The surface became cold and clammy, and death occurred from involvement of the vagus, (Drs. Ketchum and Toxey, report to the Mobile Medical Society).[1]

Cases of paralysis from poisoning by arsenic and lead have been so frequently reported, and are so fully described in the text-books that I deem it unnecessary to lengthen this paper with their consideration, except to emphasize the importance of recognizing the influence of these agents in the causation of peripheral neuritis.

2. There are a number of infectious diseases which are occasionally followed by nerve disturbances eventuating in paralysis, as: Diphtheria, scarlet fever, typhoid fever, tuberculosis, etc. The invasion of the nervous system by the morbific agent which caused the original disease usually manifests itself during the period of convalescence. Apprehending the true nature of the trouble, we will be able from the distribution of the paralysis to estimate with something like certainty its gravity and foresee its termination.

Diphtheritic paralysis is familiar to every practitioner of experience, and no doubt some of us have seen paralysis, with atrophy, following the other diseases mentioned.

Paralysis due to malaria is by no means infrequent; I have had several cases of this character in my own practice, and Holt, Westphal and Albutt have reported similar cases, therefore, I need not consume time in its description.

The influence of tuberculosis has been variously estimated, and while I know of no positively reliable observations confirming the suspicion that it is sometimes the principal causative factor in multiple neuritis, there is at least a marked coincidence, for in the cases reported by Joffroy, Eisenlohr, Strümpell, Webber, and Müller, phthisis pre-existed.

The influence of syphilis is not positively known, but the consensus of opinion among neurologists is that it is never the cause of multiple neuritis. Syphilitic neoplasms may invade the tract of a nerve and by pressure create a localized neuritis, but no cases have, as yet, been reported which would justify us in assuming that a widespread inflammation of the peripheral nerves is ever one of its manifestations.

3. In some cases after the most searching investigation no cause has been ascertained, but they occurred under such circumstances as to justify the assumption that they were due to cold, damp, exposure, fatigue and bad hygienic surroundings. How these act as causative factors in impressing the nervous system so profoundly, we do not know, and can only hope that future researchers will remove the obscurity which now surrounds them.

III. A young girl, 17 years of age, who had previously enjoyed good health, but who had been subjected to considerable fatigue from watching, hard work, and constant walking, was taken, in May, 1886, with chills, sweats, and headache. On the 25th of the same month there en-

1 These two cases are reported as typical cases of multiple nueritis. I have notes of seven cases occurring in my own practice, but they are not complete, hence do not utilize them.

sued numbness, anæsthesia, and paresis in both legs, and also in the three fingers at the ulnar side of both hands. May 31, there was paresis of the left facial nerve. During the following week the paresis increased in extent and intensity so that not only all the facial branches of the facial nerve were found paralyzed, but also all the muscles of the neck, of the trunk, and of the extremities, were markedly paretic. The bladder and rectum were normal. There were no contractures, no spasms. On the 14th day of the disease the temperature was 104° F. On the 18th day there was an amelioration, anæsthesia diminished, but was replaced by hyperæsthesia. On June 27th there was complete paralysis of all the branches of the facial nerve, and considerable paresis of those of the neck, trunk, and extremities. There were anæsthesia of the skin of the face and lower extremities, pain on pressure of the nerve-trunks, and in the muscles of the face and extremities, and slight atrophy of the muscles of the hands. All the reflexes were abolished. R. D. was total in the face, and partial in the extremities. There was no fever. Intelligence was good. After a few days the anæsthesia subsided. July 8th, the facial paralysis was decidedly better. July 13th, the abdominal reflexes, and July 27th, the plantar reflexes returned. On July 23rd she could take a few steps. September 29th, recovery complete, the patient walking without difficulty.—*Brazelius*, *Nordiskt Medicinkst Arkiv.*, 1887.

IV. H. G., aged 16 years, of good physique, and up to present illness enjoyed good health. Family history negative. While returning from his daily labor, that of a saw-mill hand, was caught in a shower of rain, wetting his clothes. On reaching home he failed to change his clothes but went to bed, and slept soundly all night. Upon rising next morning he detected a feeling of numbness and tingling in both feet. This progressively advanced to the knees. At the same time he suffered from intense pain in the limbs. On the third day his hands, wrists and arms became similarly affected. I saw him on the sixth day, and his condition was as follows: He stands with great difficulty. When he attempts to walk he staggers, not, however, from cerebral disturbance, the incöordination being due to paresis of the muscles of the legs. There is hyperæsthesia from the feet to the knees, although there are circumscribed points of anæsthesia in the same surface area. The grasp is feeble. The reflexes are absent. Romberg's symptom is not present. On the seventh day the paralysis was complete from the toes to the knees, and from the fingers to the elbows; and there was great weakness in the muscles of the thighs and arms. Wrist-drop and foot-drop marked. There was no response to the faradic current. The galvanic current showed R. D. complete in the feet, legs, hands and forearms. On the eighteenth day the paralysis being complete in the extremities, the inflammation invaded the trunk and the muscles of respiration became involved, and death ensued on the nineteenth day of the disease.

In arriving at a diagnosis in multiple neuritis, it is necessary to exclude those forms of paralysis due to lesions of the cord, namely, acute anterior polio-myelitis, tabes dorsalis, and diffuse myelitis.

From polio-myelitis anterior it may be differentiated by the onset being more gradual, accompanied by pain and numbness, tenderness in the muscles, and the persistency of the sensory symptoms. Should the symptoms not be clearly defined and the paralysis situated in muscles supplied by a single nerve, the case is evidently one of multiple neuritis. The paralysis in multiple neuritis gradually advances, while in polio-myelitis it, often after the onset, subsides in the muscles first affected.

Ataxia, loss of knee-jerk, pain and sensory disturbances (including loss of muscle sense), Romberg's symptom and optic neuritis are common to tabes dorsalis and multiple neuritis. In the latter the relatively rapid onset of the ataxia, the prominence of numbness and anæsthesia, instead of lightning pains, the extreme degree of anæsthesia, tenderness of the muscles and nerves, the occurrence of paresis with atrophy, the R. D., and the absence of bladder and sexual symptoms, will indicate the nature of the case. Ataxia occurs in neuritis only in cases due to poisoning by alcohol or arsenic, or after an attack of diphtheria. Return of the knee-jerk and the course of the case to recovery favor neuritis.

Diffuse myelitis is an extremely rare disease, and Leyden has affirmed that

such cases are neuritis. In multiple neuritis the functions of micturition and defecation are never affected. Girdle sensations are rare, and bed sores with cystitis have never been observed. It is rare for the paralysis in neuritis to advance from the legs to the thighs and trunk, and then to the arms, as it does in myelitis.

The prognosis is dependent upon the amount of nerve tissue involved, as indicated by the distribution of the paralysis and is, in most cases, favorable. There are three indications to be met by treatment, namely:

1. The removal of all agencies which have been influential in precipitating the attack, or of those which, if not removed, are likely to intensify it.

2. The relief of the sensory trouble, more especially the pain.

3. To improve the tone of the nervous system in order to secure a return of its functional integrity.

(1) Alcohol in its various forms should not only be prohibited, but a strict surveillance should be exercised over the patient to prevent his obtaining it. This is important and is specially emphasized because we cannot, in this disease, trust to the honesty of patients or their servants. As I have endeavored to show when speaking of the symptomatology of alcoholic neuritis, those affected are unreliable, resorting to every expedient—even lying—to deceive the attendant. But while the patient may not be able in person to obtain alcohol, by promises or threats, he can frequently induce servants to violate the expressed orders of the attendant. Therefore, every safeguard should be thrown around the patient, because, upon the total abolition of his bibulous habits depends, to a great extent, his recovery. This should, consequently, be impressed in no uncertain manner upon the minds of relatives and friends. Cases due to other causes should be placed in the most favorable surroundings to secure an absence of everything calculated to produce or aggravate the disease.

(2) For the relief of pain I can speak with confidence of the salicylates and bromides. These are to be given in large doses. The salicylate of sodium in fifteen grain doses, repeated every two or three hours, will be required to allay the pain, while the bromides appear to subdue the nerve perturbation so frequently seen in these cases. Opium is seldom required, but occasionally the pain is so severe as to require morphia hypodermatically, and it would be the refinement of cruelty, amid so much agony, to refuse the relief which this drug furnishes. In cases where malaria is a causative factor, quinia in full doses is indicated.

(3) To bring about a restoration of nerve function and to repair the damage to the nervous system, perfect, absolute rest is necessary. The surroundings of the patient should be made cheerful and pleasant in order to encourage that condition of mental equipoise and comfort so essential for nerve nutrition. Tonics, as strychnia, arsenic, iron and coca are indicated. The administration of arsenic has in the hands of most observers yielded excellent results, and should be used continuously for a long time. Strychnia, being a pure nerve tonic, may also be given with benefit. Among those who have had the largest experience in the treatment of this disease, iodide of potassium and the preparations of mercury have seemed to be without curative effect, in some cases even exercising a pernicious influence.

In order to restore the nervous system to its originally healthy condition there are two agents, which, if judiciously used, promise much. I refer to massage and electricity. The extremely tender condition of the muscles and the hyperæsthesia of the skin may, for a time, make the use of massage an impossibility, but as this undergoes amelioration gentle friction should be begun and continuously used, and as the normal condition of sensation is secured kneading should be persistently employed. Where the hyperæsthesia and tenderness are severe the use of cooling lotions, or hot water applied on cloths sometimes affords relief.

Electricity, so valuable in many morbid conditions, marked by paralysis, should be used with judgment, since it is a two-edged remedy, either proving of great benefit or lasting injury. In multiple neuritis it subserves two purposes, namely, to aid in nerve regeneration, and to re-establish the normal conductivity of the nerve. The first object is best attained by the use of the galvanic current, which should be mild, ten minutes being sufficient for each application. This should be used daily, its maximum intensity being attained slowly, without interrup-

tion. To accomplish the second object the faradic current of moderate intensity will give the best results. To exercise the muscles and to prevent the atrophy consequent upon non-use, most writers recommend the interrupted galvanic current.

With the methods of treatment detailed the management of multiple neuritis promises to be eminently successful, and day after day the benefit derived will be more and more perceptible, until at last nerve regeneration is secured, muscle tone improved, and the health of the patient perfectly restored.

COMMUNICATIONS.

CRIMINAL ABORTION.*

WM. H. PARISH, M. D.

In submitting a paper this evening upon the subject of criminal abortion, I must refer to some extent to the law relating to it, and I shall do so with no little hesitation in the presence of the learned legal gentlemen with us.

I am very forcibly reminded of something I read during my college days, in one of those dead languages which we learn so slowly and forget so quickly—namely, that he who is ignorant of the science of warfare should not discuss military matters in the presence of Hannibal—so I, ignorant of law, might well be silent in reference to matters of law in the presence of that legal Hannibal, our very able District Attorney. But I hope he will correct me when in error, and I am sure that he and the other legal gentlemen present, and our Coroner, Mr. Ashbridge, will present in a most interesting and instructive manner, the correct relations, under the law, of the physician to cases of criminal abortion, when the after-treatment comes under his charge.

The practice of destroying the fœtus *in utero* is not of modern introduction, but is recorded in history from the earlier nations, with the sole exception of the Jews. Aristotle and Plato defend it (*Travels of Anacharsis* v. p. 270; *Ibid.*, iv., p. 342). It is mentioned by Juvenal, Ovid, Seneca, and Cicero, and denounced by the earlier Christians. It was common in Europe through the Middle Ages and still prevails among the Mohammedans, Chinese, Japanese, Hindoos; and it has been so extensively resorted to in most of the nations of Africa and Polynesia that it is doubtful if more have died in these countries by plague, famine, and the sword.

In approaching the consideration of criminal abortion the first query which very naturally presents itself is, "What constitutes criminal abortion?" In attempting to reply to this question we must not confound the different interpretations given to the term abortion. In medical language the word indicates delivery prior to the viability of the child, or it is restricted by some to delivery prior to the formation of the placenta; in other words, it is limited to delivery during the first six months or the first three months of pregnancy. In law this term is not thus limited, but is applied to delivery at any time prior to intrantion maturity.

The expulsion of the ovum, fœtus, or child by criminal violence, at any period of utero-gestation, is regarded as a miscarriage or abortion in law. Criminal abortion, then, is criminal delivery prior to maturity. What constitutes criminal abortion as distinguished from non-criminal abortion? Wherein rests its criminality under human or Divine law?

"Abortion" has been legally defined thus: "Any person who does any act calculated to prevent a child from being born alive is guilty of abortion. The intention constitutes the crime, not the means employed. The drugs may even be harmless." He, then, who resorts to any procedure, however harmless in itself, with the intention of producing an abortion, is guilty.

If the pregnant woman, with or without the advice of another, administers to

* Read before the Philadelphia County Medical Society, March 22, 1893.

herself a drug or resorts to some mechanical procedure with the intention of producing an abortion, she is herself guilty and liable to punishment under the law, even though the drug or the procedure be itself harmless.

If she voluntarily submits to the use by another or mechanical means which she knows are intended to produce on her an abortion, she is guilty along with him who uses the instrument or other means.

In order that an attempt to produce an abortion may constitute a felony, it is not necessary that the woman be pregnant—even though she be not pregnant, the intention constitutes the crime.

I will not argue before this society the great moral criminality of what is known under the law as criminal abortion. The medical profession looks upon this crime as one of the most heinous, and as closely allied to infanticide. He who is believed guilty of such a crime could never be received into membership in this or any other medical society; or if a member should so far forget his high calling as to be guilty of this crime, his expulsion would quickly follow upon the presentation of adequate evidence of his guilt.

The physician who resorts to criminal abortion does so in the most secret manner, for he knows not only that he is punishable under the law, but he also knows that professional ostracism will make him forever an outcast from the medical profession.

Undoubtedly many criminal abortions are produced by legalized practitioners of medicine, but in this State the law legalizing the practice of medicine is a very lax one, and in some States there is no law determining who shall practice medicine. I do not believe that criminal abortion is frequently performed, even ever so secretly, by men or women of recognized professional standing; but that it is at times produced by some such members is certainly the case, as the records of the criminal docket show. The habitual abortionist, if a legalized practitioner, is nearly always one around whom suspicion, at least, has rested, and this suspicion has been sufficient to debar him from that affiliation with the worthy members of the medical profession which constitutes to a large degree the stamp of professional respectability. The medical profession draws a wide distinction between a legalized practitioner of medicine and a worthy, reputable physician. Unfortunately, this distinction is not sharply drawn by some lay minds.

Graduates of the best medical schools have proved false to their noble avocation, and have brought dishonor upon themselves and, to a certain degree, discredit upon the profession of medicine. But this experience is not limited to our profession—a like experience occurs in the sister professions of theology and of law, and, in fact, we may say in all avocations of life.

There are those, however, who produce, or attempt to produce, criminal abortion who are not legalized practitioners of medicine—are not practitioners of medicine at all. Often such persons are exceedingly ignorant; they know nothing of the anatomy concerned; they possess no manual skill in the manœuvres undertaken; they have only the most vague knowledge of the injuries which may be inflicted; they know nothing, or almost nothing, of the effects of the drugs administered; they only believe that certain procedures and certain drugs have the reputation of producing abortion; yet he who attempts to produce an abortion always knows that what he is doing is criminal.

Criminal abortion, however, is not infrequently produced or attempted by the pregnant woman herself. I think that such women are not always cognizant of the fact that they are liable to the law for such an act. Each one knows that if she commits the crime on another she is amenable to punishment; but for a self-produced abortion she seems not to know that she is punishable.

A few words in reference to the justifiable production of abortion or of premature labor by members of the medical profession. That the production of delivery before the viability of the child, *i. e.*, before the end of the sixth month, is at times justifiable, is recognized in the courts and by the medical profession. But the conditions which justify such a radical procedure are not numerous.

Whenever it is necessary to terminate pregnancy in order to save the life of the mother, such a procedure is justifiable; if not thus necessary, the procedure is criminal. I grant that there is room for difference of opinion in the medical pro-

fession as to what conditions justify the production of abortion. The resort to an abortion may be reprehensible though not criminal; for instance, when it is performed by a practitioner of medicine under the mistaken, though honest, opinion that an abortion is necessary to save the life of the mother. It is quite generally accepted that there are cases of disorders of the kidneys, or of the heart, of degenerations of the ovum—as myxoma of the chorion and polyhydramnios—and very rarely instances of uncontrollable vomiting, in which the production of early or late abortion is demanded and justifiable, because it is necessary to save the life of the mother, and also because the death of the mother always involves the death of the embryo and usually that of the child approaching maturity. The authoritative works on "Medical Jurisprudence" class among the conditions justifying abortion, extreme pelvic deformity. Although this statement was a proper one at one time, it is not so at present, in my opinion.

The very favorable results of the Cæsarean section, and of its modification, the Porro operation, and of symphysiotomy so recently introduced into this country—the results, I say, of these operations are now so very favorable, both to the mother and to the child, that it is time to eliminate even extreme pelvic deformity from the list of conditions justifying early abortion. The law leaves it quite entirely to the medical profession to determine what constitutes justifiable abortion, either early or late. The responsibility in this direction thus placed upon us is a very weighty one, and the privilege conferred with it should be exercised with the utmost discretion. I have, in a very few instances, felt that the physician was getting very close to criminal ground when he produced an abortion under the plea of justifiability. For instance, a lady pregnant three months wanted an abortion produced, and so did her husband, because she, having had one very painful labor, had great dread of another labor in advanced pregnancy. They both expressed great fear that insanity would develop if her pregnancy was not terminated. Her physician asked me in consultation. We decided that an abortion, was unjustifiable. She returned to her former home in a distant city and there the abortion was produced by a regular practitioner. I saw a letter from this physician in which he attempted to justify on medical grounds, not only this abortion, but also two previous ones on the same lady. His plea was that of justifiability because of apprehended insanity. Such and similar cases seem to me to quite merge into criminality. Professional opinion in reference to what constitutes justifiable abortion should be so firmly crystallized that criminal abortion could not be performed under a false plea of justifiability.

As to the frequency of the occurrence of criminal abortion, it is impossible to give any statement of even approximate accuracy. Secrecy is so closely associated with its performance, that it is impossible to arrive at more than the crudest opinion as to the frequency of its occurrence.

I suppose every physician of some reputation as an obstetrician or gynecologist has applications from those desiring that an abortion should be produced. Probably a half-dozen such applicants call upon me during each year. Doubtless the same women visit other physicians on like errands. Also, nearly every physician is called in to take charge of the after-treatment of cases of criminal abortion. He will suspect some of them to be criminal, but in most instances he is unable to assert that the abortion is or is not a criminal one. Many cases of early criminal abortion do not come under reputable professional care at any period of their course. Even all the fatal cases are not recognized as criminal. For these reasons it is impossible to do more than to form an opinion that criminal abortion is performed with considerable frequency. All statistical statements as to the frequency of criminal abortion are, however, valueless, and are merely expressions of opinion.

It is well recognized that criminal abortion brings to the patient enhanced dangers—dangers greater than those pertaining to accidental or justifiably produced abortion. The increased dangers are due to the character of the manœuvres and to the drugs resorted to. The mechanical measures are often carried out in a bungling, unskilled manner, and without regard to the liability of conveying a septic poison. Often drugs are used, which, when given in too large quantities, endanger the life of the patient whether or not an abortion is pro-

duced. The woman, desirous of securing secrecy, often does not call in a physician sufficiently early to enable him to prevent a fatal result.

The methods of producing, or of attempting to produce, criminal abortion are numerous and widely diverse in character. Of the drugs resorted to in this country, probably the ones most frequently used, and also the ones most likely to effect the result aimed at, are the preparations of ergot and of cotton-root. These drugs act by stimulating directly the contraction of the uterus. I have known a patient to treasure up a bottle of ergot left over from her labor, and to successfully partake of its contents at the incipiency of her next pregnancy. But even these drugs usually fail to effect an abortion at any period of pregnancy. Among other drugs frequently administered are aloes and savine. The entire list of medicines occasionally resorted to would be a long one—among them may be mentioned elaterium, croton oil, colocynth, gamboge, cantharides, arsenic, strychnine, corrosive sublimate, and other forms of mercury; pennyroyal, tansy, black hellebore, and not a few others, some of which are active poisons, others are dangerous in large quantities, and some are harmless. None of them produce abortion except occasionally, and then only through their injurious effects upon other organs or upon the general system. Some of them will produce the death of the patient without producing an abortion.

Tardieu, in his classical treatise, gives numerous cases of abortion produced, or attempted, by mechanical means. The professional abortionist usually dilates the cervix with a metallic dilator, and introduces a slender instrument into the uterus and punctures the membrane—or he may use the latter instrument without previous dilation of the cervix. Very usually, after the membranes have been punctured, he dismisses the patient and an abortion comes on in generally from three to ten days.

The more modern method of the criminal abortionist of advanced ideas is to dilate the uterus with graduated dilators, under ether, and at once to empty the uterus with all antiseptic precaution, usually receiving the woman into his private hospital for this operation. A lady applied to one of the medical men who advertised in the New York papers. He admitted her into his hospital in New York City, and practiced the immediate removal of the ovum. She returned to Philadelphia at the expiration of a week's absence.

But sometimes the operator is ignorant and unskilled, and a great variety of instruments have been carried into the uterus: wooden skewer, crochet-needle, hair-pin, knitting-needle, a weaver's spindle, whalebone, wire, umbrella-ribs, penholders, catheters, bougie sounds, tents, and dilators. Tardieu speaks of the frequent use in France, of what is termed a hedgehog, which I believe is a slender instrument having near the end a number of bristles, which lie close to the handle when introduced into the uterus, but expand after introduction, and which, when rotated very effectually, break up the ovum, but which has proved disastrous also to the mother. Electricity is also effectually resorted to, one pole being usually introduced into the uterus.

Injections of corrosive or other irritant substances into the vagina are occasionally resorted to by the patient or by an ignorant abortionist. I have known a patient to produce an exfoliation of almost all of the epithelial lining of the vagina, by means of a strong solution of alum, without producing an abortion. Injections of different fluids, even water, into the uterus are resorted to, and if the membranes are largely detatched or ruptured, abortion inevitably follows. In a few instances the most violent measures, such as the introduction of the hand into the uterus and attempts to drag out the entire uterus, have produced most disastrous effects.

What lesions do we find following attempts at criminal abortion? Naturally, from the variety of the means resorted to, these are various, and may be numerous in an individual case. In one authentic case the patient herself carried an umbrella-rib into the uterus, perforated its wall, entered and passed upward and through the abdomen, through the diaphragm and into the lungs. She did not desist in her efforts until coughing of blood and troubled breathing alarmed her. She concealed her manœuvres, and the umbrella-rib was found *in situ* in a post-mortem examination. During pregnancy the physiological softening of the uterine

tissue permits the easy passage of a somewhat sharp instrument through it into the peritoneal cavity, and generally with resultant fatal peritonitis. When mechanical means are resorted to, if perforation of the uterus does not occur there is usually, though not invariably, laceration —it may be a slight one—of the neck of the uterus or of the vagina. Rupture of the vagina or of the uterus has occurred from the introduction of the hand. Abscesses at various points in the uterus or in close proximity to it may follow. Blood-poisoning with local inflammations constitute the pathological conditions following many cases of criminal abortion. When drugs have been administered, gastric and intestinal inflammation may result, and evidences of such be seen after death.

It is not usually difficult to determine that an abortion is in progress; but it is by no means an easy matter to determine with certainty, from the examination of the patient during life, whether or not the abortion is criminal in character. Even fatal perforations of the uterus are not usually recognizable during life. The statements of the patient may give this information, but she may, and usually does, deny that any attempt has been made to produce an abortion. Her statements, if accepted, would usually be misleading. Hence cases which recover, and the very great majority do recover, can usually be only diagnosticated as probably criminal abortions.

In the lesions found post-mortem, there is no characteristic evidence that the abortion has been a criminal one, excepting the wounds, which are usually, though not always, present in such cases as have resulted from the use of mechanical means. Even then the history of the case must be looked into, for the abortion may have been innocently produced by a reputable physician, who had failed to recognize the existence of pregnancy. Lacerations of the vulva, perineum, or vagina, may result from violent sexual intercourse, and excessive or violent intercourse is not an infrequent cause of abortion in the young.

The after-treatment of criminal abortion must be according to the peculiarities of the case. If the abortion is incomplete, the indications are absolute to immediately empty the uterus and to render it aseptic. Here the expectant treatment is fraught with great danger. Such cases usually call for the utmost skill of the expert to effect the recovery of the woman.

Most frequently the underlying cause of a fatal result is septic infection or blood-poisoning. The traumatism produced is in itself usually slight and insignificant, but septic poison develops in the retained fragments of the products of conception, or is carried into the genitals by the abortionist. Blood-poisoning and the associated inflammatory lesions result.

Abdominal section with ablation of the uterus and its appendages, or of the appendages alone, may be necessitated.

When a patient suffering from a criminal abortion is sent to a hospital, it should be to one having a maternity or a gynecological ward; otherwise, the best treatment may not be secured.

In the management of cases of criminal abortion, the physician is often placed in a most trying position. If, perchance, he has been informed by the patient, or, if in his examinations he has discovered that measures or drugs have been resorted to with the view of producing an abortion, what becomes his duty under the law? Here we would like to have an expression of the views of the Coroner, the District-Attorney, and the other lawyers present.

Is it incumbent upon the physician to notify the officers of the law, that an abortion has been produced, or attempted, illegally? If he does not thus furnish this information, to what extent, if any, does he render himself a *particeps criminis* under the law? Should the information thus gained in the practice of his profession be held sacred in deference to the good name of his patient, who is usually, though not always, more sinned against than sinning, or in deference often to the fair fame and happiness of the other members of the family?

I believe that very often the physician does all that is in his power to conceal both the fact that an illegitimate pregnancy has occurred, and also that an abortion, even though criminal, has resulted. Is the physician then acting with justice to himself, and with a proper appreciation of his duties under the circumstances? Is it incumbent upon him to become an informer?

I know that in this State the information gained in the practice of his profession, and necessary to the proper treat-

ment of his patient—I know that such information is not privileged, but may be extorted from him in our courts. Yet must he voluntarily convey this information to the officers of the law? Or shall he draw a distinction between the fatal and the non-fatal cases? Shall he report only the fatal cases to an officer of the law, withholding his certificate of death in such instances and letting the Coroner investigate the circumstances? Certainly, if the case is about to terminate fatally the proper information should be given in order that an ante-mortem statment may be secured, and undoubtedly also no physician should give a death certificate in any case in which the death has resulted from what he strongly suspects or believes or knows to have been a criminal abortion.

These rules are in accord with justice to the physician whose reputation is at stake, and are also in accord with law and the welfare of the community. But if the patient is recovering, is it required by law, or is it in accord with the general welfare of the community, that information bearing upon the character of the abortion should be formally brought by the physician before the officers of the law? I will answer the question in the negative, and will ask the gentlemen present to tell us in the discussion whether or not I am correct. In my opinion the physician should not become an informer.

I will further say, that he should not elicit or extort from the patient any information bearing upon her criminality, other than that which is necessary for his guidance in the performance of his professional duties. He must not perform the functions of a detective.

In all serious cases of abortion, especially if criminal, the physician should secure another physician in consultation for the protection of his own reputation, as well as for the welfare of the patient. Let the physician remember, also, that he can examine the patient's genitals only with her consent. If he, by an exercise of force, secures such examination, he renders himself liable to punishment by legal process.

The consideration of the measures which may tend to diminish the number of criminal abortions becomes very important in every large city, for it is believed that where the population has become concentrated, there this crime occurs with greatest frequency. These conditions or habits of life, which diminish the number of marriages, increase the number of illegitimate pregnancies and the number of criminal abortions. But many such abortions occur in the married, and largely in proportion to the tendencies on the part of the married to indulge in expensive habits of life beyond their financial abilities.

The disgrace and shame attendant upon illegitimate pregnancy or maternity is the impelling motive on the part of the great majority of the unmarried. A recognition of the difficulties and of the disgrace attendant upon the care of an illegitimate child, on the part of its unmarried mother, impels some to secure criminal abortion.

With all, however, there is an underlying immorality, usually on the part of both sexes, which leads up to the commission of an act as unnatural as it is criminal. The preservation of the purity of morals, then, of the youth of both sexes constitutes the only efficient safeguard against the occurrence, in any community of criminal abortion—other measures are adjuncts only.

Suturing of Divided Tendons.

Dr. A. H. Meisenbach, Professor of Surgery, Marion-Sims College of Medicine, St. Louis, Mo., says:

In the suturing of divided tendons in order to obtain good results the following indications must be met, viz.:

1. The utmost care in carrying out complete aseptic and antiseptic measures.
2. Enlarging the wound to such an extent that a free field for operation is obtained; extensive opening of a sheath, if necessary, to easily catch up retracted tendons.
3. Care in suturing the corresponding cut ends with silk or catgut, preferably catgut.
4. The ends of tendons, if ragged, may be resected, so as to get smooth edges. If not enabled on this account to approximate the ends, with a suture intervening, good results may still be expected.
5. Careful suturing of the sheath with continuous catgut suture, leaving an opening for drainage at the site where tendons are sutured.
6. Appropriate position on a splint, the parts being so placed as to relax the sutured tendons.—*North Carolina Med. Jr.*

THE LAW OF CRIMINAL ABORTION IN PENNSYLVANIA.*

LORENZO D. BULETTE, OF THE PHILADELPHIA BAR.

The differences of opinion among the courts of England and the various States, as to the stage of gestation at which the common law crime of abortion may be perpetrated, causes any extended examination of their decisions to partake of a speculative rather than practical character; especially so, in view of the fact that the question is now very generally settled by statute, and nearly all indictments are founded on these statutes, the provision of which and the judicial interpretation thereof, even on similar provisions, vary in the courts of the different States.

And when, in addition to this, it is recalled that the law of this State, in the severer view it has always taken of the crime and the milder view it has always taken of the consequences thereof where they result in the death of the woman, presents peculiarities which sharply differentiate it from the law of other States, thus causing it to stand practically alone, it will be apparent that the course most fruitful of results, for the purposes of the present occasion, is to confine our inquiry to the law of criminal abortion as it stands to-day under the Criminal Code of Pennsylvania and the decisions of her courts interpreting that code.

The first and only legislative enactment aimed at this crime appears as the 87th and 88th sections of the Penal Code, which is known as the Act of March 31, 1860.

Section 87 is in the following language:

"If any person shall unlawfully administer to any woman, pregnant or quick with child, or supposed and believed to be pregnant or quick with child, any drug, poison, or other substance whatsoever, or shall unlawfully use any instrument or other means whatsoever, with the intent to procure the miscarriage of such woman, and such woman, or any child with which she may be quick, shall die in consequence of either of said unlawful acts, the person so offending shall be guilty of felony, and shall be sentenced to pay a fine not exceeding five hundred dollars, and to undergo an imprisonment by separate or solitary confinement at labor not exceeding seven years."[1]

Section 88 is in language as follows:

"If any person, with intent to procure the miscarriage of any woman, shall unlawfully administer to her any poison, drug, or substance whatsoever, or shall unlawfully use any instrument, or other means whatsoever with the like intent, such person shall be guilty of felony, and being thereof convicted, shall be sentenced to pay a fine not exceeding five hundred dollars and undergo an imprisonment by separate or solitary confinement at labor, not exceeding three years."[2]

Both these sections are new in the criminal statutes of Pennsylvania, and contrasting them broadly it is clear that § 87 is intended to meet the case of the death of a pregnant woman following any criminal intent to procure her miscarriage, or the death of the child with which she may be pregnant. It also meets the case of the death of a woman from drugs administered, or instruments applied, with the intent to produce abortion, where such woman is not actually pregnant.

Section 88 punishes the administration of drugs or the use of instruments with intent to procure abortion, although no abortion is actually produced, and although the female survives the operation. This section, it was hoped by the commissioners who drafted the Penal Code, might tend to put a stop to crime of too frequent occurrence.[3]

With this much for the language and purpose of the statute, we next proceed to the decisions of the courts explaining and interpreting it; and these may be arranged for convenience and clearness under the following heads:

1. Definition and Degree of the Crime;
2. Interpretation of the Statute;
3. Means Employed and the Intention;
4. Legal Responsibility of the Obstetrician in his Relations with Abortion.

Of Definition and Degree of the Crime.—Miscarriage, both in law and philology, means the bringing forth the fœtus before it is perfectly formed and capable of living.

Abortion is synonymous and equivalent to miscarriage in its primary meaning; and when it is brought about with a malicious design, or for an unlawful purpose, it is a crime in law.

*Read before the Philadelphia County Medical Society, March 22, 1893.

1 Act, March 31, 1860, § 87; Purdon's Digest, § 156, p. 431.

2 Act, March 31, 1860, § 88; Purdon's Digest, § 157, p. 431.

3 Report of the Commissioners on the Penal Code, p. 25.

Any person, therefore, who does any unlawful act calculated to prevent a child from being born alive is guilty of criminal abortion. This is justly regarded as an offence of great enormity; because, to procure the miscarriage of the woman interferes with and violates the mysteries of nature in that process by which the human race is propagated and continued. The attempt, by wicked means, to interfere with that process and destroy the fruit of the womb thus becomes a crime against nature, closely allied to murder, and, therefore, deserving of severe and ignominious punishment.[4]

"It is not," says Mr. Justice Coulter, "necessary that the mother have quickened to constitute the crime of committing abortion. But, although it has been so held in Massachusetts and some other States, it is not, I apprehend, the law in Pennsylvania, and never ought to have been the law anywhere. It is not the murder of the living child which constitutes the offence, but the destruction of gestation by wicked means and against nature. The moment the womb is instinct with embryo life, and gestation has begun, the crime may be perpetrated."[5]

In this connection it must be borne in mind that, at common law it was never a punishable offence to perform an operation on a pregnant woman with her consent, before the child quickened; nor was it murder, at common law, to take the life of a child at any period of gestation, even in the very act of delivery, or while any portion of the child, except the umbilical cord, remained within the vulva.[6]

Preliminary to a discussion of § 87, which applies to the crime of committing an abortion resulting in the death of either or both mother and child, it may be profitable to contrast the degree of criminality of the offence, resulting in the death of the mother, as viewed by the common law, with the degree of criminality of the same offence as viewed by the law of Pennsylvania as it existed previously to March 31, 1860.

Of the degree of turpitude of this offence, one of the most learned and humane sages of the common law, Sir Matthew Hale, gives the following as the doctrine ruled by him at Bury Assizes in the year 1672:

"If a woman be with child, and any gives her a potion to destroy the child within her, and she takes it and it works so strongly that it kills her, this is murder: for it was not to cure her of a disease, but unlawfully to destroy her child within her; and, therefore, he that gives a potion to this end, must take the hazard, and if it kills the mother, it is murder."[7] And the same doctrine has been held in more recent times.[8]

In Pennsylvania, however, it was decided in a more lenient spirit that although death was not intended, yet, the acts are of a nature deliberate and malicious, and necessarily attended with great danger to the persons on whom they are practiced; and, consequently, those who perpetrate them are answerable for their results. And although by the common law such a crime would, therefore, have been murder, yet in Pennsylvania it can hardly be regarded as exceeding that crime in the second degree, unless there existed in the perpetrator of the mischief an intent as well to take away the life of the mother as to destroy her offspring. It is the nature of the intention with which the criminal act is committed that constitutes the great distinguishing feature between murder as it stands at the common law and murder as it is understood in the criminal code of this Commonwealth. Where the illegal act, which produces death, is malicious and perpetrated with an intent to take life, the offence becomes murder in the first degree, and punishable with death; where no such attempt is apparent, the crime is reduced to murder of the second degree, and punished by penal imprisonment.

At common law the death of the mother following criminal abortion is murder, not because the agent accomplishing the act intended to kill the female, but because the act being unlawful in itself he is held responsible for all its results. In Pennsylvania, however, that murder only is felony of death, where the act producing the homicide is not only unlawful but perpetrated with an intent to kill the victim of the crime. The common law murder fol-

lowing criminal abortion is the exact kind of crime which the legislature intended by the act of 1794 to reduce to the grade of murder in the second degree; being a homicide arising from an unlawful act, unaccompanied with an attempt to take away life.[9]

Thus stood the law relating to this offence prior to the Abortion Act of March 31, 1860. But since that time the Supreme Court has decided[10] that the effect of § 87 of that Act was to take the crime therein specified out of the class designated as murder in the second degree, and make it a felony of lesser grade and prescribe the punishment therefor. As a consequence of this decision, if a person cause the death of a woman in attempting to produce a miscarriage, he cannot be indicted for murder; and this is the law in Pennsylvania at this time.

Of the Interpretation of the Statute.—As compared with the offence specified in § 87, that described in § 88 is complete without the death of either the woman or the child. "In both cases," says Mr. Justice Green, "the grade of the offence is the same, viz., felony. In both cases the acts done are the same. In the first, if those acts are followed by the death of the mother or child as a consequence, that is, in the relation of effect to a cause, a difference results in one of the penalties imposed. The possible fine is the same, but the possible imprisonment is longer—seven years instead of three. The facts which constitute the crime are precisely the same in both cases, to wit, the administering the drug or using the instrument with intent to produce a miscarriage. It follows that the death is no part of the facts which go to make up or constitute the crime. It is complete with the death or without it. The death, therefore, considered in and of itself, is not a constituent element of the offence. It may happen or it may not. If it does not happen, a certain possibility of penalty follows. If it does happen the same character of penalty follows, but with a larger possibility, not a certainty, in one of its items. This seems to be a precise expression of the difference between the cases provided for in the two sections.

"In case the woman does die in consequence of the unlawful acts, the crime charged and tried is not homicide in any of its forms, but the felony of administering a drug or using an instrument with intent to procure a miscarriage. In its facts and its essence it is the same crime that is charged and tried if no death results. The death, when it occurs, is an incident the sole purpose of which is to determine whether the imprisonment of the defendant may be longer than when death does not occur. The crime is as fully completed without the death as with it. The death, therefore, is not an essential ingredient of it. Its function under the statute, when it occurs as a consequence, is not to determine the *factum*, or the character, or the grade of the crime, but the character of the penalty to be endured by the criminal."[11]

Of the Means Employed and the Intention.—The terms of the statute specifying the means employed are so sweeping and comprehensive that one could scarcely suppose a doubt in this respect possible: "any drug, poison, or other substance whatsoever, or shall unlawfully use any instrument or other means whatsoever," is the language of the statute. But the question did arise during the trial of an indictment charging the accused with prescribing and advising the use of immoderate and excessive exercise with intent to induce abortion. And the court, in answer to the objection of defendant's counsel that such means do not constitute any offence under § 88, contending that the words defining the crime, "or shall use any instrument or other means whatsoever," imply some act to be done by the defendant and not by the woman herself at his instigation, or under his advice, persuasion, or influence, said: "We are not prepared to adopt the view of the law presented by the defendant's counsel, for the reason that such an interpretation would greatly abridge what we conceive to be the remedial design of the statute, and, to a great extent, frustrate the expressed intention of its framers. If a person intent on inducing abortion must not only prescribe the drug, but with his own hand put it to his victim's lips, or, after contriving the mechanical means, must to

11 Railing *vs.* Commonwealth, 110 Pa. St. 104 (1885).

moral constraint superadd physical force, we can readily perceive how the abortionist may practice his nefarious schemes with impunity in the very face of the statute. The defendant, according to the evidence, contrived these means and used the prosecutrix as a blind instrument in rendering them efficacious; what she did was as much his act as if she had been moved to it by outward constraint." And, as the evidence produced by the prosecution tended to prove the charge of advising the use of immoderate and excessive exercise to induce the abortion, the court instructed the jury that such means were within the intent and meaning of § 88 and that they were used by the defendant just as much so as if he had been present and employed physical instead of moral force.[12]

And in another case it was said that if any person administers any matter or thing to a woman who is pregnant or quick with child, with intent to produce an abortion, and the woman or child shall die, notwithstanding the matter or thing administered is but a crumb of bread, such person is within the statute and may, upon proper evidence, be convicted.[13]

The question, therefore, is one of intention and not of the means employed; it is whether the drug was used or the means were employed with the intent to induce abortion.

It is not necessary that the substance administered have some inherent tendency to accomplish the imputed design. If a person administers any harmful substance to a pregnant woman, or to one supposed at the time to be pregnant, with the intent to procure her miscarriage, although the substance administered may fail of the effect designed, and although it may have no tendency to produce such effect, he will be guilty of the offence of criminal abortion within the contemplation of the statute.

And it is not necessary for the Commonwealth to establish beyond doubt what was the direct and immediate cause of the miscarriage; the question is whether the means employed were calculated to produce it, and with intent to do so.[14]

13 Commonwealth *vs.* Gumpert, 1 Luz. Leg. Reg., 187 (1877).

14 Acheson, P. J., in Commonwealth *vs.* W.—3, Pittsburg, 462 (1871).

Summarizing briefly we conclude: *a.* That in respect to the crime of abortion the law of Pennsylvania has always taken an advanced and enlightened view as compared with the history of the law relating to this crime in other States—its policy and first care throughout being the preservation of fœtal life and the punishment of the unlawful destruction thereof severely as compared with the punishment inflicted upon the same offence where it results fatally.

b. That the intention, not the means employed constitutes the crime, which is complete although the means employed have no inherent tendency to produce the designed effect, and although the woman be not pregnant.

c. That the crime under our statute is not homicide in any of its forms, but simply the statutory crime of committing or attempting to commit abortion; and that in its essence the degree of criminality is the same whether the results are fatal or otherwise, the only difference being a slightly increased punishment in the former case.

Of the Legal Responsibility of the Obstetrician in His Relations with Abortion.—It seems a proper addition to this statement of the law to offer also the precautions thereby suggested for the guidance of the professional conduct of the obstetrician in order to shield him from reproach, suspicion, or, perhaps, prosecution in those relations with abortion in which he is likely to be placed.

That abortion may in some cases be lawful is undoubted. This fact, while not expressed in the terms, is true as a necessary inference from the language of the statute: it is the unlawful administration of drugs and the unlawful use of instruments that is denounced by its sanctions. Any question, therefore, respecting the illegality of inducing premature labor in certain cases where the life of the woman is seriously endangered, as in deformity of the pelvis or in excessive vomiting from pregnancy, cannot now be entertained; for the means are administered or applied with the *bona fide* intention of benefiting the female, and not with any criminal design.

Says an authority:[15] "The necessity for the practice ought to be apparent; thus,

15 Taylor's Medical Jurisprudence, p. 529.

for instance, it should be shown that delivery was not likely to take place naturally without seriously endangering the life of the woman. It is questionable whether, under any circumstances, it would be justifiable to bring on premature expulsion merely for the purpose of attempting to save the life of the child, since the operation, even when performed with care, is accompanied with risk to the life of the mother. Hence, a cautious selection of cases should be made as the operation is necessarily attended with some risk to both.

"All that we can say is that, according to the general professional experience, it should place the woman in a better position than she would be if the case were left to itself. But before a practitioner resolves upon performing an operation of this kind he should consult with his colleagues, and before it is performed he should feel assured that natural delivery cannot take place without greater risk to the life of the woman than the operation would itself create.

"The non-observance of these rules is necessarily attended with some responsibility to the general practitioner. In the event of the death of a woman or child he exposes himself to a prosecution for a criminal offence, from the imputation of which even an acquittal will not always clear him in the eyes of the public."

The physician is also liable to be brought into another and different relation with abortion, that is, when he is called to attend a patient suffering from the effects of a criminal operation and the question arises as to his legal duty in order to shield himself from the consequences attending his after-acquired knowledge of the crime.

The only safe course for such physician, after being satisfied with the correctness of his diagnosis—confirmed by one, or, better still, two of his colleagues—is to lay the foundation so acquired of the crime before the prosecuting attorney of the county. But it may, perhaps, be more satisfactory to the medical profession to have the reasons for this advice set forth somewhat in detail.

In its interpretation of the two sections of the Abortion Act, the Supreme Court, as mentioned above, has decided, and expressed its opinion with some emphasis, that the two offences therein described are the same; consequently, the duty of the physician in his relations with each case, that is, whether the woman dies or survives the operation, is the same.

That Court has also decided that dying declarations are admissible in evidence only in cases of homicide; and, as the same Court has further declared, as above stated, that criminal abortion is not, in this State, homicide in any of its forms, it necessarily follows that the dying declarations of the victim of an abortion are not admissible in evidence at the trial of a person charged with the latter crime. And as it frequently happens, from the peculiar circumstances surrounding cases of this sort, that this is the only evidence, it would be worse than useless to make any exposure of a matter, the only effect of which would be to bring additional shame and disgrace upon the innocent family and relatives of the victim, with no possibility of convicting the accused.

Hence will be seen the wisdom of first informing the prosecuting officer of the county rather than the coroner or the police authorities. For it is the duty of the prosecuting officer, or district attorney, as he is called in this State, to prosecute offenders against the law. He is skilled in the law and able to weigh such evidence and judge of its probative effect; and if, for any legal reason, such as stated in the preceding paragraph, the facts constituting the information be either incompetent or insufficient as evidence, that reason will be known to the district attorney, and unnecessary public exposure will be avoided. On the other hand, the subordinate officers referred to are not required to be skilled in the law; their jurisdiction is limited and the sphere of their official duty circumscribed, so that it often happens that unnecessary publication of such facts result from a mistaken notion of their duty. Moreover, they are, in a sense, merely a part of the machinery in the hands of the district attorney, that may be employed by him in bringing criminals to justice.

From all of which it is clear that the proper course for the physician, in every instance, is to lay the information that comes to his knowledge, of a criminal abortion, before the district attorney. This may be done either in person or by letter to that officer, setting forth the facts, and it then becomes his duty to take whatever subsequent action such

facts may seem to warrant. In any event, the physician is thus relieved of further personal responsibility in the matter.

Furthermore, such a course on the part of a physician does not render him liable, either to the imputation of being an informer or a detective, nor is he chargeable with a violation of professional confidence. The reason is, that the Legislature has declared criminal abortion to be a felony, and to conceal a felony is an offence known as misprision of felony, which, under the Criminal Code of Pennsylvania, renders the person guilty thereof liable, if convicted, to be punished as an accessory after the fact, by a fine not exceeding five hundred dollars and to undergo an imprisonment, with or without labor, at the discretion of the court, not exceeding two years.[1]

Consequently, the physician, who, in the face of the powerful and persuasive influences against disclosure that are sometimes brought to bear upon him in these cases, and who, although imbued with a fine sense of the sacredness of the relation of physician and patient, and the obligation thereby imposed to preserve the secrets thereof inviolate, yet yields obedience to the higher law, not only discharges a high and solemn duty to the public by making such information as will aid in the punishment and prevention of a crime, so dark and hidden, that strikes at the very foundations of society, but also relieves his own conscience from any share in the guilt of the principal offender, and at the same time pursues the plain course marked out by law to shield himself from any liability to prosecution by reason thereof.

The observance, therefore, by the medical practitioner of these simple prudential measures, either when it becomes necessary to induce premature labor or when he is called to attend the victim of an abortion will not only free him from the liability of any criminal charge but commend him in the eyes of the law.

1 Act, March 31, 1860, § 180; Purdon's Digest, § 356, p. 469.

A DISCUSSION OF THE LEGAL ASPECT OF CRIMINAL ABORTION.*

WILLIAM W. PORTER, Esq.

It is with hesitation that I participate in the discussion of this subject, because the topic is somewhat remote from the matters which daily engross those of us of the legal profession who devote our attention to questions of a so-called civil character. When, however, we go down to the foundation of the matter, there is little difference in kind between proceedings for the punishment of crime and the settlement of civil disputes. A crime is simply a wrong, a deflection from moral rectitude; but a wrong of so heinous or grievous a character as to affect the public as well as the individual upon whom the direct injury is inflicted.

The great Commentator on the common law has said "in all cases the crime includes an injury. Every public offence is always a private wrong and somewhat more. It affects the individual, and it likewise affects the community."

The crime of abortion, or attempting to procure abortion, is a wrong committed by one individual upon another, but it is of so horrible a character that a punishment for its commission has been inflicted by legislation in order to prevent its frequent occurrence.

The legislation in Pennsylvania upon the subject of criminal abortion is contained in two sections of the Act of March 31, 1860, known as the Penal Code. It is applicable to the case of death following an attempt to procure abortion. The full text of the section is as follows:

Section 87.—If any person shall unlawfully administer to any woman, pregnant or quick with child, or supposed and believed to be pregnant or quick with child, any drug, poison, or other substance whatsoever, or shall unlawfully use any instrument or other means whatsoever, with the intent to procure the miscarriage of such woman, and such woman, or any child with which she may be quick, shall die in consequence of either of said unlawful acts, the person so offending shall be guilty of felony, and shall be sentenced to pay a fine, not exceeding five hundred dollars, and to undergo an imprisonment by separate or solitary confinement at labor not exceeding seven years.

*Read before the Philadelphia County Medical Society, March 22, 1893.

Section 88 of the same act provides for the penalty to be imposed for procuring or attempting to procure abortion where death does not ensue. The full text of the section is as follows:

> If any person, with intent to procure the miscarriage of any woman, shall unlawfully administer to her any poison, drug, or substance whatsoever, or shall unlawfully use any instrument, or other means whatsoever, with the like intent, such person shall be guilty of felony, and being thereof convicted, shall be sentenced to pay a fine not exceeding five hundred dollars, and undergo an imprisonment by separate or solitary confinement at labor not exceeding three years.

In so distinguished an assembly of the medical profession little interest can be felt in any attempt to interpret the meaning of these legislative enactments. No reputable member of the medical profession would consent to participate in the commission of so heinous a crime as attempting criminal abortion. Were the statute book barren of any enactment there would be no danger from such a source of any transgression of what a true moral sense imposed. I do not, therefore, propose to enter upon any discussion of the direct provisions of this act. It may be well, however, to learn what the Supreme Court said in an opinion rendered ten years before the adoption of the present existing legislation, in the case of Mills *vs.* Commonwealth, 13 Pa. St. 933, defining in what the crime consists. The opinion of the court was delivered by Mr. Justice Coulter. He says "The error assigned is that the indictment charges the defendant with intent to cause and procure the miscarriage and abortion of the said Mary Elizabeth L——,instead of charging the intent to cause and produce miscarriage and abortion of the child. But it is a misconception of the learned counsel that no abortion can be predicated of the act of untimely birth by foul means.

Miscarriage, both in law and philology, means the bringing forth the fœtus before it is perfectly formed and capable of living; and is rightfully predicated of the woman, because it refers to the act of premature delivery. The word abortion is synonymous and equivalent to miscarriage in its primary meaning. It has a secondary meaning, in which it is used to denote the offspring. But it was not used in that sense here, and ought not to have been. It is a flagrant crime at common law to attempt to procure the miscarriage or abortion of the woman, because it interferes with and violates the mysteries of nature in that process by which the human race is propagated and continued. It is a crime against nature which obstructs the fountain of life, and therefore, it is punished. The next error assigned, is that it ought to have been charged in the count that the woman had become quick. But, although it has been so held in Massachusetts and some other States, it is not, I apprehend, the law in Pennsylvania, and never ought to have been the law anywhere. It is not murder of a living child which constitutes the offence, but the destruction of gestation by wicked means and against nature. The moment the womb is instinct with embryo, life and gestation has begun, the crime may be perpetrated. The allegation in this indictment was therefore sufficient, to wit: 'that she was then and there pregnant and big with child.' By the well-settled and established doctrine of the common law, the civil rights of an infant *in ventre sa mere* are fully protected at all periods after conception."

The only interest which the reputable practitioner can have in the subject of criminal abortion may be discussed in answer to two questions, both arising out of a professional call to attend a patient upon whom an abortion has been attempted. In such a case the medical attendant is interested to know:

I. What personal risk he assumes in attending upon such a case.

II. What moral or legal obligation he incurs in connection therewith.

I. He does incur some risk in such a case.

1. He may, unless he steers his course carefully, be involved as an accessory after the fact.

The Act of March 31, 1860, also contains in Section 180, the following provision:

> Every principal in the second degree, or accessory before the fact, to any felony punishable under this act, for whom no punishment has been hereinbefore provided, shall be punishable in the same manner as the principal in the first degree is by this act punishable. Every accessory after the fact to any felony punishable under this act, for whom no punishment has been hereinbefore provided, shall, on conviction, be sentenced to a fine not exceeding five hundred dollars, and to undergo an imprisonment, with or without labor, at the discretion of the court, not exceeding two years. And every person who shall counsel, aid or abet the commission of any misdemeanor, punishable under this act, for whom no punishment has been hereinbefore provided, shall be liable to be proceeded against and punished as the principal offender.

What an accessory means in the case of an abortion it is difficult to say, inasmuch as the books seem to contain no precedent, and the courts have given no expression of opinion. While this fact adds to the difficulties of discussion and determination, it also may be looked upon as an evidence that the danger to the physician in such a connection is small, inasmuch as none seem to have been pursued by litigation.

It practically means that the physician must be careful when called in to treat a patient upon whom such an operation has been performed, that he shall do nothing to assist in the purpose of the perpetrator of the operation, except that which is necessitated by the condition of the patient, to save life or restore health. The best safeguard in a case where the physician is compelled to complete the operation (if such a case ever arises) is to have another reputable practitioner in consultation and present at the time of treatment.

2. One who has committed an abortion resulting in death cannot be convicted of murder. In the case of Commonwealth *vs.* Railing, 113 Pa. St. 37, decided in 1886, it was held that the 87th Section of the Criminal Code took the crime therein specified, namely, procuring miscarriage resulting in the death of the child or woman, out of the class designated as murder, and made it a felony of lesser grade, and prescribed the punishment therefor; hence if one cause the death of a woman in attempting to procure miscarriage, he cannot be indicted for murder.

3. The physician in cases of abortion, may by the action of evilly-disposed persons be involved in the commission of a crime perpetrated wholly by another. When a physician is charged with such a crime the evidence of one who is charged as a co-defendant may be used against him.

A somewhat recent case which has appeared in the reported decisions of the Supreme Court of Pennsylvania, is that of Cox *vs.* Commonwealth, 125 Pa. St. 94. The decision was filed March, 1889. This was the case of a Dr. Cox, of Easton, Pa., who was accused of having procured an abortion upon the person of a young unmarried woman who was taken to Easton for the purpose of having the operation performed. There was little to connect the physician with the commission of the act (except the fact that he had engaged a nurse for the patient in advance of her arrival in Easton), beside the testimony of one Evans, who was indicted with the physician as a party to the crime. Evans was called as a witness by the Commonwealth, and testified that he had made arrangements with Dr. Cox to perform the operation at Easton, and that he subsequently accompanied the young woman to Easton to a hotel. He knew nothing of the actual operation. Upon this testimony, in large measure, the Doctor was convicted of the offence, the Supreme Court, by Mr. Chief Justice Paxson, conceding that juries may convict upon the uncorroborated testimony of an accomplice.

A physician *might* thus be convicted on the uncorroborated testimony of a self-confessed accomplice, provided such accomplice was able or willing to testify to all of the facts leading up to a commission of the act and to the act itself. In the case cited, the commission of the act itself was independently proven.

An evilly disposed man *might*, in order to trouble and perhaps blackmail a physician, falsely confess himself an accomplice, and thus, practically unsupported, secure a verdict of guilty against a physician whose only connection with the case might have been treatment of a patient who had committed the crime upon herself. Again, the patient herself might be a confederate and expect to be a participant in the reward which the blackmailer hoped to force from the physician for silence. It is true that an alleged accomplice must persuade the jury by whom the case is tried that he is telling the truth, and it is difficult to so persuade a jury without some corroborating evidence. I speak here, not of what is likely, but what is possible to happen. There may be blackmailers who would go so far. The method to avoid the danger is the association of a consulting physician immediately on being called to treat the case, or if it shall seem to the physician an aggravated case of wrongdoing by a person other than the sufferer, to report the case to the police authorities.

4. A most important question was for some time an open one, namely, whether the dying declarations of a person upon whom an abortion has been committed are admissible in evidence. It was supposed to be set at rest by the case of Railing *vs.*

Commonwealth, 110 Pa. St. 100, decided in 1885, where it was distinctly held that such declarations could not be accepted in evidence on the trial of one charged with the crime.

I observed by the Philadelphia *Public Ledger* of this morning that an act has been introduced in the Senate of Pennsylvania, making dying declarations admissible as evidence. I have been unable to secure a copy of the proposed act.

In view of the fact that such a bill is, or soon will be, under discussion, a quotation of some length from the opinion of Mr. Justice Green, of the Supreme Court of Pennsylvania, delivered in the case above referred to, showing the reasoning by which the result was reached by the court, may be permissible. He says:

"The principal question in this case is that which relates to the admissibility of the dying declarations of Annie F———. The defendant was charged with administering to her a drug with intent to procure a miscarriage, and it was also charged that her death resulted as a consequence. There were four counts in the indictment, and all of them charged the death of the woman as a result of the defendant's unlawful act. It is entirely unquestioned that dying declarations are admissible only in homicide cases, as a rule, and that the death of the deceased must be the subject of the charge, and the circumstances of the death the subject of the declaration: 1 Greenl. Ev., Sec. 156, 13th ed., Whart. Cr. Ev., Sec. 276; Whart. Am. Cr. Law, Sec. 669 et seq. It is equally unquestioned that there is no grade of homicide involved in this case, the offence charged being the one commonly know as abortion. It is argued, however, with much force, that the death of the woman, when it occurs, is a necessary ingredient of the offence under our statute, and therefore brings the case within the rule above stated. It is claimed that the death is in part, at least, the subject of the charge. In one sense this is true. But the question is, Is it so in the real sense of the rule which controls the subject? That inquiry involves the necessity of an examination of our criminal statute against abortion. It consists of two sections, the 87th and 88th of the Criminal Code of 1860." Here the learned judge states the substance of the two sections. He then continues: "In the last case the offence is complete without the death of the mother or child. In both cases the grade of the offence is the same, felony. In both, the acts done by the prisoner are the same. In the first, if those acts are followed by the death of the mother or child as a consequence, that is, in the relation of effect to a cause, a difference results in one of the penalties imposed—the possible fine is the same, but the possible imprisonment is longer, seven years, instead of three. The facts which constitute the crime are precisely the same in both cases, to wit., the administering the drug, or using the instrument, with intent to procure a miscarriage. It follows that the death is no part of the facts which go to make up or constitute the crime. It is complete with the death or without it. The death, therefore, considered in and of itself is not a constituent element of the offence. It may happen or it may not. If it does not happen a certain possibility of penalty follows. If it does happen, the same character of penalty results, but with a larger possibility, not a certainty, in one of the items. This seems to be a precise expression of the difference between the cases provided for in the two sections. This being so the question recurs, is the difference between the two of such a character as to change the application of the rule of law relating to the admissibility of dying declarations? Of course, they are not admissible if death does not result as a consequence from the unlawful acts. Therefore if the woman should subsequently die from some entirely different and independent cause, her dying declarations in relation to a prior miscarriage would be clearly incompetent. In case she does die in consequence of the unlawful acts, the crime charged and tried is not homicide in any of its forms, but the felony of administering a drug or using an instrument with intent to produce a miscarriage. In its facts and in its essence it is the same crime that is charged and tried if no death results. The death, when it occurs, is an incident, the sole purpose of which is to determine whether the imprisonment of the defendant may be longer than when death does not occur. The facts which constitute the crime may not be proved by any declarations of the woman when death does not follow, or when it follows from

some other cause. Why, then, should the very same facts be proved by such declaration when death does result? Not because it is a homicide, and the rule as to dying declarations admits them in such cases ; because it is not a case of homicide in any point of view. Not because the death is the subject of the charge, for the charge is the attempted or accomplished miscarriage by means of a drug or instrument. That crime is as fully completed without the death as with it. The death, therefore, is not an essential ingredient of it. Its function under the statute, when it occurs as a consequence, is not to determined the *factum,* or the character, or the grade of the crime, but the character of the penalty that should be endured by the criminal. Of course, if the statute had declared that when death resulted the offence should be manslaughter or any other grade of homicide, the case would be entirely different. Then the death would be an essential ingredient of the offence, and would be the subject of the charge, and the rule as to dying declarations would apply. But such is not the case, and we do not think it wise to enlarge the operation of the rule so as to embrace cases other than homicide strictly. The objections to the admission of such testimony are of the gravest character. It is hearsay, it is not under the sanctity of an oath, and there is no opportunity for cross-examination. It is also subject to the special objection that it generally comes from persons in the last stage of physical exhaustion, with mental powers necessarily impaired to a greater or less extent, and at the best, represents the declarant's perceptions, conclusions, inferences, and opinions, which may be, and often are, based upon imperfect and inadequate grounds. Nor is the reason ordinarily given for their admission at all satisfactory. It is that the declarant in the immediate presence of death is so conscious of the great responsibility awaiting him in the near future if he utters a falsehood, that he will, in all probability, utter only the truth. The fallacy of this reasoning has been many times demonstrated. It leaves entirely out of account the influence of the passions of hatred and revenge which almost all human beings naturally feel against their murderers, and it ignores the well-known fact that persons guilty of murder, beyond all question, very frequently deny their guilt up to the last moment upon the scaffold."

II. We come now to the second grand division of the subject, namely, the obligations resting upon the physician or surgeon who is called upon to attend in a case of criminal abortion. Having satisfied that the injury to the patient has not been self-inflicted, should the physician conceal the truth or make it known?

In answering this question he must consider:

1. His duty to his patient.
2. His duty to his profession.
3. His duty to the public at large.

In discussing these matters we are met with ethical rather than legal considerations. I have been able to find nothing as a guide, either in legislative elements or in cases decided by the courts.

Therefore, what is here said is only by way of suggestion and discussion. The determination of the questions of duty in each case must be relegated to the forum of individual conscience.

1. The duty to the patient.

Take the following as an illustration: A reputable head of a family has called in the services of the family doctor to attend a sick daughter. The physician soon has evidence sufficient to indicate a case of criminal abortion. He learns from the patient in confidence that a certain physician, or her lover, or both, have assisted in producing her serious condition.

There is a plain duty to the girl and to her father, to prevent scandal, and yet an act has been committed which has been pronounced by the State law a felony. Silence means that the criminal must go unpunished. It is a condition that, unfortunately, men of the medical profession have sometimes to face.

There is no statutory penalty imposed for silence. Can it be doubted that the physician in such a case is justified in holding his peace *so long as a fatal termination of the illness is not impending.*

Information received by counsel from his client is regarded by the law as a privileged communication, and he cannot be compelled to divulge the information so received. In the case of a physician, however, the rule of the common law seems to be that he can be compelled to divulge communications received from his patient. There is to my mind, in this distinction between the professions, an il-

logical discrimination, and I believe that in most cases a physician would rather undergo the punishment imposed by a court for silence than violate the professional confidence. Some of the States (for example, New York) have adopted legislation making confidential communications between patient and physician privileged, and I would respectfully suggest that measures to secure such legislation in Pennsylvaina might well be taken, both for the protection of the medical practitioner and the sanctity of the professional relation.

2. The duty to the profession.

A loyal physician holds his profession in high honor. To have men within its ranks who will lend themselves to the commission of crime is a disgrace. Not to punish them will only lead them to greater confidence in their ability to escape punishment and encourage them in their infamous behavior.

This consideration has weight in determining the course of duty. The conclusion, therefore reached, is that where the professional obligation to the patient will permit, duty to the profession must impel disclosure (at least to the profession, and better, to the police authorities) of the name of the wrongdoer.

3. What of the public generally?

The physician is a citizen. He owes a citizen's duty to the community at large. If he or any other citizen knows that a crime has been committed by a particular person, and fails to bring the criminal to justice, he falls short of his obligation. It is true that in the smaller offences (especially those involving property) we can hardly be expected in all cases coming under our knowledge to see that each wrongdoer is punished.

When the urchin, with our eyes upon him, pilfers an apple from the corner stand, we do not feel that we have committed a grievous sin of omission if we do not personally inform the first policeman, or if we do not ourselves pursue the little culprit to his capture, in order to insure his punishment.

If, however, we see serious bodily injury inflicted, or murder impending, who of us would not, at personal inconvenience or peril, see to the capture and punishment of the perpetrator.

If the patient is to recover from the effects of the crime perpetrated on her, and the injury is slight, by analogy, there is some justification for silence.

If she is to die, and the injury is thus greater, silence is not only dangerous, but it is without justification. It is not easy, certainly, to justify this conclusion, since, under the act, the criminal intent is the same in both cases, the only difference being in the result. Death from criminal abortion entails upon the attending physician who conceals it, the necessity for a written lie in the certificate which he is required to give by the registration acts. Should he certify the true cause of death, he cannot avoid publicity, and may be subjected to censure for failing to report the case sooner to the authorities. If he certifies falsely and is discovered, he runs the risk of being charged with the commission of the crime itself.

Finally, the rules of conduct may be summarized thus:

1. When called to such a case, immediately, on suspicion of criminality being aroused, call in another physician to your aid.

2. If consistent with your primary duty to the patient, report the case (even though not likely to be fatal) to the District Attorney.

3. As soon as a fatal result appears likely, report the case to the District Attorney, who (if requested) will doubtless never let you be known as his informant, but you will be enabled by other means of proof to bring a criminal to justice.

4. If you have not reported the case, and the end is death, do not be led into the giving of a false certificate of death.

In conclusion, it will be seen that what has been said is almost wholly discursive. It would ill-become a member of our profession to assume to instruct in the ethics of the sister profession. It cannot be truthfully said that the legal profession has a higher moral standard than the medical, and to each conscientious member of both must it be left to do the right as to conscience and good morals it shall appear.

"JOHN MCDUFFY, charged with vagrancy. What can you say for yourself?"

"Not guilty, your Honor."

"What is your business?"

"A Professor of bacteriology."

"Ten dollars and twenty days—no visible means of support."

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of March 22nd, 1893.

DISCUSSION ON CRIMINAL ABORTION.

HON. GEORGE S. GRAHAM: I should hesitate to add anything to this discussion were it not for the fact that there are one or two points on which I differ with those who have preceded me. I have nothing to say about the definition and the law; both have been thoroughly and amply stated. I want to call attention, first, to the question of dying declarations, and second, to the attitude of the physician with relation to this offence. I wish to call the attention of this organization to the bill that is now pending in the Legislature of Pennsylvania, intended to cover a gap in the criminal law through which more men escape conviction who justly deserve it, than through any other. I am not here to criticise the ruling of the Supreme Court, but the effect of that ruling which excludes the dying declaration from admissibility as a piece of evidence. In conversation with a gentleman, a member of this society, he suggested to me the desirability of some such law, and in pursuance of that suggestion I prepared the bill which was introduced yesterday, and therefore, the objurgations of my friend fall upon my head. The bill is plain, simple, and to the point; it provides that in all cases of prosecution for abortion where death results, the dying declaration may be admitted as evidence. It does not change the rules under which that declaration is admissible. It simply remedies what was disturbed and broken by the decision in Commonwealth *vs.* Rauck. The question was discussed in that case whether or not such declarations were admissible in prosecutions for abortion where the person died. In our county we had taken the ground that this crime involved an inquiry into the question of a death, and that, therefore, the dying declaration was admissible. We were able to convince the Judges of our Courts of Quarter Sessions that that was the true view, and there were three decisions sustaining that view. The case referred to went up from Dauphin County, and the Supreme Court reversed the decisions in the county courts and held that because of the passage of the Act of Assembly which called abortion a felony and defined it as the crime of abortion, it was withdrawn from the list of homicides, and that dying declarations were only admissible in cases of homicide. It is conceded by all lawyers that abortion did, at common law, come under the classification of homicide; a person might have been convicted at common law, according to the circumstances, of murder in the second degree or of manslaughter. It was owing to the passage of that Act, which lifted criminal abortion out of the category of homicide and placed it in a new relation to the criminal code, that the Court held that dying declarations in this kind of a case were not admissible. My friend quoted the *obiter dicta* of the Judge. That is no part of the decision and no part of the authority of the case itself. Speaking of dying declarations on the broad ground whether they should be admitted or not, the Judge said that they are the merest hear-says, and should not be permitted to appear in evidence to fasten crime. Here is an anomaly to which I direct your attention. While the Judge reasoned that they should be excluded in a crime which had been lessened and made of smaller magnitude in the eye of the law, he admitted that in the higher and graver crimes, such as murder and manslaughter, the necessity of society demanded that dying declarations should be admitted. Mark the ground on which they are to be admitted, to wit, the necessity of society. If there is a single instance of criminality in which the necesity of society demands the admission of dying declarations as a piece of evidence, it is in that most secret of all offences, the crime of abortion. Now, surely the reasoning of that learned Judge is utterly fallacious in another point. Said he: "The argument usually employed that the solemnization of the thoughts at the

idea of dissolution will cause the person to speak the truth, is not applicable, for we leave out the element of the passions of hatred and revenge." Why, gentlemen, by a parity of reasoning you would destroy all testimony, for the same line of argument, logically pursued, would make you exclude the evidence of every witness. I submit that the reason upon which dying declarations are admitted has a good foundation. It is well-known that the approach of death solemnizes the thoughts of every man or woman. They may laugh and scoff at death in health, but I tell you when they come face to face with the hour of dissolution, it must be the rare exception indeed, in which the storm of passion can dominate the soul and make one commit perjury of the worst kind, standing on the threshold of the future. I say, therefore, that dying declarations, if admissible in homicide of the higher grades, should be admitted in this offence of abortion, and I come to ask your body to pass some resolution asking for such a law.

I want to say a word about the duty of the physician. I appreciate what has been said by Dr. Parish and Mr. Porter with regard to the sentiment that gathers about the relationship of physician to patient. The picture drawn by Mr. Porter appeals to the setiments of us all, but there is only one test, and it is not the test of sentiment. It is, is the thing intrinsically right, or is it wrong? We are not considering what the law ought to be, but what it is. It is the duty of every citizen, if he knows that a crime has been committed, to make it known. If an offence is grave enough for the law to recognize and fix a penality on, you have no right to set that law aside and say that it is too insignificant for you to notice. The physician can only escape censure or prosecution by revealing the fact that an offence has been committed. It would be no defence in a court of justice for a physician to say that he kept it quiet because he wished to be a shield between a suffering female and the disgrace that might ensue. Of course, in the graver cases where death ensues, it is imperative that the matter should be reported. I ask you, laying aside sentiment, to point out a single reason why there should be a distinction between the cases where death follows and those where death does not follow. The distinction is attempted to be drawn because one is of less importance, but my answer to that is that the law does not say that it is the duty of the citizen to report only important criminal cases. Besides, both are felonies. It is his duty to report every criminal case, and the physician who learns of such a crime and conceals it, becomes an aider and abettor in the crime. Surely no man can rise and say, that on the basis of sentiment he has a right to become a criminal. That is the result, for if by concealment he becomes a *particeps criminis*, surely the duty to speak must be regarded as absolute.

Coroner Samuel H. Ashbridge: I shall not enter into this discussion from a medical or a legal standpoint, but merely from that of practical observation and with reference to the rules that we lay down in our office for the purpose of conducting cases of the character under consideration. The question has been raised whether or not these cases should be reported. During the year we have hundreds of cases reported to our office by physicians, who state that the patient is suffering from peritonitis, which they believe to be the result of operation for the induction of abortion. Such information is always treated as confidential, and the name or residence of the patient is not asked. I say to the physician that if the patient dies and he believes that the death is due to criminal abortion, it is his duty to report it. I am glad to state that there are few deaths in comparsion to the number of cases reported.

Abortions are prevalent in all communities; but I want to say, to the credit of our city, that there are fewer abortions in Philadelphia than in any other great city on this continent. One reason of this is, the high moral character of the medical profession of this city. It is rare that you find a graduate of a regular reputable medical college who will stoop to the crime of abortion.

I agree with the District Attorney in regard to the enactment of a law making dying declarations admissible. It is very difficult for us to procure unmistakable evidence unless from the victim herself. Crimes of this character are of such a secret nature that often they are only known to the victim and the perpetrator. In Philadelphia, at the present time, detection of this crime is less frequent than at

any other period, according to my knowledge. I cannot say that it is because more skill is used, but there does not seem to be any lessening of the offence. We have the opportunity of learning many things that are never published to the world —in fact, it is not our duty as public officials to reveal scandals that may come to our knowledge. If the majesty of the law has been maintained we feel that we have done all that is incumbent upon us.

Dr. Harris A. Slocum: I agree with Dr. Parish, that the diagnosis of criminal abortion is a difficult matter, except in cases of puncture, or where there are evidences of laceration where accident can be excluded.

The responsibility of the physician in treating these cases is a matter that has been brought to my mind a number of times. The District Attorney has said that it is the duty of the physician to report these cases; but if the names of the patients are insisted upon I think that there are few physicians who would not object. We know that the counsel for a criminal is permitted to retain the facts given to him by his client. Would a lawyer who was not counsel for the prisoner, but who was told the facts, be permitted to retain them?

Mr. Graham: He would have to tell them. The law says that the counsel shall not divulge the facts told him by his client, but it says the physician shall tell those given him by his patient.

Dr. Slocum: I have always been under the impression that facts of this kind communicated to a physician were to be held sacred and not divulged, and I think the majority of physicians hold the same opinion. Surely the law is unjustly discriminating when it extorts such evidence from a man whose whole duty is to relieve suffering or save life, and who is called, in an emergency, for that purpose, and that alone; yet the very one whose duty it should be to contribute to the administration of justice, and who is officially stamped for that purpose, is permitted to have knowledge of incriminating facts and to keep silent about them, even during the crucial trial in court, when every effort is apparently being made to know the truth and the whole truth.

I am glad, however, to get this official information respecting our duty in these cases, in the sight of the law. It is a point that many of us have wished to be certain about. We now know that we are confronted by the unpleasant alternatives of breaking the law or of betraying the trust reposed in us by becoming informers, and it is probable that every physician in Philadelphia, even those of the highest reputation and of the greatest integrity, will fall into one line or the other. It seems to me that in the cause of right and justice, that portion of the law which relates to this subject should be so modified as to leave some latitude to the discretion of the physician. No class of men, at the present day, is doing so much to prevent this crime as is that of medicine, and yet a representative of that class is liable, at any time, and against his inclination, to become either a criminal, in the eyes of the law, in being an "accessory after the fact," or a betrayer, in the eyes of a patient.

Dr. Eugene P. Bernardy: No matter at what stage or period of pregnancy the operation for criminal abortion is performed, *it is murder*. I know many will differ with me; the theologian and lawyer, more especially the layman. With what insignificance the idea of animate existence of the fœtus in its early stages is held by them. We, as physicians, know from the poor, ignorant, hard-working woman in our courts and alleys, to whom another child means more care and harder work, to our society women of the highest mental attainments, to whom a child is a bother in the way of her social duties. Women who would not cause the least unnecessary pain to be inflicted upon any human being or beast, will without the slightest hesitation or shame, ask that they be relieved of their (to them) troublesome burden, and, when refused, are surprised and become indignant, and reply: "Why, it is only a month old, and it certainly is not alive." If not alive, could it continue its growth, until, eventually, from the seemingly microscopic inert mass, springs forth that wonderful creation, man? I ask again, could a dead mass perform such an act? To grow, we must be animate; to be animate, we must have vitality. Life means a soul. At what time of pregnancy does this mystical union of the animal and spiritual natures of the human being occur? At the moment of conception, quickening, or birth? On this point theologians are divided. Many be-

lieve that the soul enters the body at the moment of quickening, and previous to that moment the fœtus was soulless. Others believe that the soul is imparted to the child at the moment of its birth. I cannot believe that God performs such imperfect work. I believe that the embryonic mass, surrounded by the deciduæ, vera and reflexa, has as much a soul as the child on the day of its birth, and on this conviction have I always practiced, looking upon the performance of a criminal abortion as being nothing less than murder.

Quickening is a mere circumstance in the physiological history of the fœtus. It is uncertain in its periods, sometimes making itself sensible at three months, at other times four or five months, and in a large percentage of cases not at all. Many women have been delivered of children that have never quickened. Are these children to be considered as soulless?

On this very point were laws made in England under George III, in 1803, when it was ordained that the procuring of an abortion of a female *not quick* with child is felony, to be punished by fine, imprisonment, or exposure in the pillory, or that the criminal may be publicly or privately whipped, or transported beyond the sea for any term not exceeding fourteen years. The same act also declares that to procure abortion after quickening is murder, to be punishable with death. This law has of recent years been somewhat modified, and at present the law in England is that the procuring of an abortion at any period of pregnany is a felony, to be punished by transportation for fifteen years or for life, or by imprisonment for three years.

The laws with regard to the punishment for this crime vary in the different countries, some imposing punishment more or less severe, according to the stage of pregnancy. The laws of Pennsylvania look upon the act as criminal in all its stages. On the trial of a murderer for performing a criminal abortion which resulted in the death of the mother, the judge, in charging the injury, declared that "at common law the crime is murder. Every act of procuring an abortion is murder, whether the person perpetrating the crime intended to kill the woman or merely feloniously to destroy the fruit of her womb." The procuring of an abortion is "a base and unmanly act;" it is a crime against the natural feelings of man, against the welfare and safety of woman, against the peace and prosperity of society, and against the Divine command, "Thou shalt not kill." It is murder.

WILLIAM W. PORTER, ESQ.: I have not had an opportunity of reading the bill to which reference has been made. I am not here to oppose it; but I would caution the medical profession to think twice, or at least once, before it indorses it. The adoption of such a law amounts to this: that when you are attending a case of this kind, where death seems to be approaching, you must metamorphose yourself, change from the medical practitioner to the practiced detective, or run to a public officer, in order that the dying declaration may be obtained from one who has intrusted to your care body, health, and even that which is more sacred—the secret of her vanished honor. I throw this out as a suggestion. I should like to see the act before I say anything directly concerning it.

The District Attorney has dwelt upon the duty of the physician in regard to reporting these cases. I have listened to hear what punishment is to be inflicted for silence, and I have listened in vain. Is silence criminal? God forbid! It is golden. There is in the criminal code no penalty for silence, impelled by a sense of honor, in such cases.

MR. GRAHAM: I would suggest to my friend that there is such a thing as misprison of felony or the concealment of a felony. There is a duty upon the citizen to disclose a felony that comes to his knowledge. The question is one of abstract duty; sentiment cannot overcome it. I have not discussed the question whether the lawyer and physician should be put on the same basis. The present position of the physician under the law is different from that of the lawyer. The law has said that the lawyer's relation with his client is confidential, while the physician is not protected. So long as this is the case, the duty of the physician to report a felony is absolute.

MR. PORTER: When we talk about the right of the lawyer to keep silence, it means that if, on the witness stand he is asked a question, he may decline to reply on the ground that the communication was confidential from a client. If the

physician, on the stand, declines to reply, the court may punish him. This, however, is totally different from saying that a physician, *not* on the witness stand, who is repository of a secret, is bound to divulge it. Even if he knows of the crime as a citizen there may be strong grounds of justification in withholding such knowledge, but when the knowledge is gained through the professional relation, if you can discriminate in good morals, between the rights of the lawyer and those of physician, I cannot.

My First Case.

The following from the *Medical Age* is from the pen of Dr. G. A. Williams, and is reproduced in full: My first case of obstetrics was somewhat unique, but I had attended two sessions and considered myself quite skillful and scientific. My preceptor took me in charge one day, and introduced me to an old colored lady who was about to be confined. This lady carried considerable weight with her—I believe she weighed about three hundred pounds—and, as the weather was very hot, the case proved to be quite interesting. I remembered having read somewhere that the doctor should sit down quietly and read a book, wait for matters to develop, and not be too meddlesome. I found an old almanac, but could not read a word of it, for I had an attack of globus hystericus; and as I was trembling and gasping for breath, two old colored ladies came in—one of them was Ol' Auntie Smith, who was known as a great nurse. Ah! but wasn't this an angel's visit? The patient now had strong pains, and the nurse said: "Doctah, is you gwine to try a pain?" Never having seen a case before, and not understanding her, I tried to look wise and answered: "Bimeby." In a short time the labor was more advanced, and the old nurse called upon me again: "Please, doctah, yo' bettah 'zamine dis yer lady." Accordingly, I passed my hand somewhere in the region of the vulva, and suddenly there was a tremendous gush and splashing sound which almost demoralized me; still I congratulated myself upon my bravery in this supposed case of "terrible hemorrhage," and, not wishing to alarm the bystanders by exposing my ghastly, blood-stained hand and arm, I remained petrified, as it were, in the same position. Just then the old nurse said: "Doctah, I reckon the wattahs is done broke, ain't dey?" Ye gods! what a relief this was to me! I suddenly remembered that there was such a thing as the rupture of the membranes, and, withdrawing my hand, it is needless to say I had more respect for that old nurse than for any lady I ever saw. The baby was born immediately, and, with some encouragement and instructions, I recovered myself sufficiently to tie the cord. The baby was placed in a cradle, and the nurse exclaimed: "Yo' pufessional gen'lmen ginally waits 'bout a half ouah fur de afterbuf, don't you, doctah?" "Yes," said I, but, owing to the great strain upon my nerves, the reaction had now come on, and I hadn't the remotest idea of what the old nurse meant. We didn't have to wait, however, for the afterbirth came away in a minute or two, and the patient herself exclaimed: "It's done come, Auntie; it's done come." The old nurse removed the afterbirth and soiled clothing carefully, and took a nice clean bandage and applied it snugly around the patient. And this was the end of one of the easiest and most natural cases I ever attended. While washing my hands in an adjoining room, I over-heard the old nurse saying: "Dat ar young gen'lman's a mighty fine doctah; he 'minds one ob de doctahs down Souf, wen I lived in ole Virginny." These good old souls have long since passed away and crossed the river where they are now resting under the shade trees.

EDITORIAL.

EXTRA-UTERINE PREGNANCY.

In the March issue of the Annals of Gynecology there appear two articles dealing with ectopic gestation that are well worthy of more than passing notice. The first paper reports four cases dealt with after modern surgical methods; the second paper is the notes of a case that occurred in the practice of an eminent member of the profession in the beginning of the present century. The contrast between the two is great. On the one hand there is the short quick removal of the misplaced product of conception, and on the other is the old waiting policy, resulting in an invalidism of nine years and ending in the discharge of the fœtal bones from the bladder with a fistulous tract between the bladder and rectum.

The abdominal surgeon has good reason to be proud of the advances of his science and in no direction more than that of extra-uterine pregnancy. A few years ago the coroner's physician of Philadelphia presented a statement showing the number of women who perished from this accident. A short time afterwards he was obliged to confess that the number was being decreased greatly every year by the life saving methods of the surgeon.

In the practical consideration of the subject it matters little whether such a condition as ovarian pregnancy does or does not exist. It has been denied on one hand by competent observers and as earnestly insisted upon by others equally skilled. After all it is not the hair-splitting methods of the pathologist that most concern the practitioner but the general welfare of his patients. From his standpoint the different forms exist only as curious variations of the disease.

The possibility of the occurrence of the accident should be always before the general practitioner for on him rather than the specialist devolves the making of a diagnosis. In many cases the symptoms are so plain that he who runs may read, and yet again they are masked to such an extent that even Tait was led into implying that it was folly to attempt to diag

nose extra-uterine pregnancy before rupture. The case may present all the symptoms of pregnancy and point to the occurrence of an ectopic conception from the very first, or the woman may be seized on the street or in the performance of her household duties by a sudden rupture and fall as if struck by a rifle ball. Between these two extremes there exists every variety. There may be all the classical symptoms; belief in the occurrence of pregnancy, morning nausea, swelling and tenderness of the breasts, followed by slight pelvic pain with some bleeding and the discharge of shreds of membrane, leading the unwary to imagine that a miscarriage has taken place; or, in contrast to this, there may be the lightening-like stroke of sudden and uncontrolled intra-abdominal hemorrhage which may be the first intimation that pregnancy existed.

Cases of extra-uterine pregnancy rarely come to the abdominal surgeon for diagnosis. That is made by the family physician and the surgeon is called on merely to save the life. That the diagnosis is not always easy the utterances of some of our ablest and most skilfull diagnosticians are witness. Pyosalpinx has been found where an ectopic pregnancy was expected and vice versa. The uterine cavity has been scraped and cauterized in the attempt to check the hemorrhage following a supposed abortion which, after all, was an unsuspected extra-uterine pregnancy, as revealed at the operation performed to save the patient's life by a surgeon who recognized a pelvic mass and knew that sound surgery demanded its removal.

The profession is still divided into two camps on the subject of section and removal of the sac before rupture, supposing the case be diagnosed. The difficulties of diagnosis are so great and the conditions that may be mistaken for extra-uterine pregnancy so many that the safest plan in a suspected case is to operate rather than to trust to the uncertain mercies of electricity. The electricians point with pride to reputed cures by their favorite agent, but they are unable to bring proof to bear that they were really dealing with an ectopic gestation. Injections of lethal substances into the sac have fortunately become ancient history, more to be wondered at than the practices of some old mediæval leech, half astrologer, half physician.

After rupture there is only one treatment—section and the ligature of the bleeding vessel with removal of the sac. On this point there is a full consensus of opinion. A quick operation with thorough irrigation of the abdomen, followed by glass drainage gives the patient the best chance for recovery. It were just as rational to refuse to ligate a spurting artery in the leg or arm as to trust the hemorrhage from a ruptured tubal pregnancy to nature's care.

Continued Administration of Digitalis.

In a recent paper on this subject (*Va. Med. Mo.*) Dr. F. M. Brooks says: I do not think that digitalis is a specially dangerous medicine, and am of the opinion that it may be safely pushed continuously till the pulse rate drops to 45 in the minute. I think digitalis one of the best slow heart tonics, and am much in the habit of giving it in such conditions as typhoid fever, phthisis, the later stages of pneumonia, etc., in conjunction with alcohol in some form. My experience has led me to believe that, as a rule, physicians fail to comprehend that digitalis must be given steadily and in increasing doses, till the object desired is gained or the drug found unsuited to the case. I think it, with one other drug—quinine—the only absolutely safe antipyretic for use in the acute fevers of children.

"So SHE married a man who lived in a distant city? How did she happen to become acquainted with him?"

"She saw his portrait in a medical advertisement in a newspaper and fell in love with it."—*Cape Cod Item.*

TRANSLATIONS.

THE PATHOGENY OF DIABETES.†

Chauveau and Kaufmann (*Gaz. Méd. de Paris*, Feb., 1893) regard the pathogeny of diabetes as one of the most important subjects in progressive general physiology. The glycemic function plays a most important rôle in the nutritive activity. The blood studied in a fasting subject constantly contains glucose. The subhepatic veins contain most of the sugar of the economy, and the venous blood of the general circulation is always less rich in glucose than the arterial blood. This physiological sugar is, therefore, in an incessant state of formation and destruction. It is formed in the liver (Cl. Bernard) and destroyed or transformed in the capillary networks intermediary between the arteries with red blood and the veins with black blood (A. Chauveau). It is this condition of the blood which is expressed by the term *glycemic function.* This is without doubt an improper term because it implies a manifestation of activity, a movement, while it in reality is applied to a sort of static state. The true glycemic function consists in active nutritive changes which prepare, transform and utilize the sugary materials of the blood. This state of the blood is commonly designated by the term *glycemia.* The terms *hyperglycemia* and *hypoglycemia* are also readily used, applied to cases of exaggeration or of diminution of the normal or physiological glycemia. The glycemic function, therefore, represents the *ensemble* of acts which tend to maintain with the permanence of the glucose in the blood, an equilibrium between the dispensing and the production of this substance. It is well known that *glycosuria*, the essential symptoms of diabetes mellitus, is due to *hyperglycemia,* that is to say an abnormal accumulation of sugar in the blood. But what is the immediate cause of this hyperglycemia? Does the blood become too rich in sugar because the tissues cease to appropriate this substance of the nourishing fluid for the needs of the nutritive acts which occur in the heart of the anatomical elements? Does this fluid enrich itself, or the contrary, in sugary material, because the liver turns more of it into the circulatory torrent, or even because other organs become auxiliary to the liver in the sugar-forming function? In other words, is it the consuming of the sugar which is arrested or the production which is increased when this substance accumulates in the blood of the diabetic in sufficient quantity to provoke an elimination by the senal passages? The answer to this remains still in suspense.

The method employed by the authors in their effort to solve this problem rests entirely upon the results of the comparative analyses of the arterial and venous bloods of the general circulation. Three cases may present themselves; either the venous blood becomes, as in the normal state, less rich in glucose than the arterial blood, and then the hyperglycemia should be placed to the account not of a default in the consumption of the glucose, but to an excess in its production, or the two bloods show themselves nearly equally rich in sugar, which necessarily implies a poor using of this substance in the capillary networks and places in this default of consumption the cause of the hyperglycemia; or finally, the venous blood becomes more sugary than the arterial blood which indicates positively that the hyperglycemia is due to a production of glucose on the site in all of the tissues of the economy. To assure exactitude of the comparative results of the analyses of the two bloods the authors took care to observe:

1. That the two bloods should be gathered simultaneously and in the same amounts.

2. That they were treated exactly in the same way.

3. That the operations in general, particularly the dosage of the glucose by the standard fluid should always be done by the same manipulator.

In the physiological state the comparative analyses of the arterial and venous bloods practiced under the conditions

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

above mentioned, never fail to demonstrate that the venous blood is less rich in sugar than the arterial. This same inferiority of the venous to the arterial blood in respect to the quantity of sugar is noticed in all of the deviations of the glycemic function which are provoked by a lesion of the central nervous system. This inferiority likewise shows itself in the hyperglycemia which follows extirpation of the pancreas. The authors will demonstrate this by presenting in a future report the results of the analyses in each particular case.

HERNIA ISCHIATICA.*

The following case is reported by Schwab (*Arch. Générales de Mèd.,* Julie 92.) The patient, female, age 31, sought relief at the hospital for a large swelling which had developed gradually in the right gluteal region. The patient had noticed a small swelling, size of a pigeon's egg, four and a half years ago which, however, gave her no discomfort and disappeared on assuming the recumbent posture.

Since two and a half years there has been a rapid enlargement of the swelling with inability to reduce it. At the present time it reaches to the hollow of the knee and is 25 centimetres long, 23 centimetres wide, and has the circumference of 62 centimetres; at its pedicle it measures 47 centimetres.

It was painless upon pressure and produced no disturbance in the action of the bowel and bladder.

Diagnosis: Fibro-lipoma of the gluteous maximus.

Operation: On cutting through the swelling a hernial sac was found in the middle, about the size of a fist, which contained loops of small intestines. Reposition of the intestines, ligation and separation of the sac, the stump receded into the pelvic cavity through the upper portion of the incisura ischiatica. A close examination of the growth revealed a second pocket with thickened walls containing a yellowish, serous fluid; the finger could be easily passed through this opening into the abdominal cavity; it was distinctly separate, but along side of the first. The examination of the growth, which weighed more than seven pounds, proved that it was chiefly composed of fibrous tissue, in which myxomatous and muscular tissue could be traced; there was little or no fatty tissue found.

The recovery was retarded at first by the discharge of gangrenous shreds from the depth of the wound and, before it was entirely closed, it was noticed that urine passed out in small quantities. At the same time catarrh of the bladder set in and almost the entire secretion of the kidneys passed out through this fistulous opening.

This condition, however, soon improved, the fistula closing until only a few drops of urine passed out per day, and the patient was discharged as cured.

The author has collected 17 cases from literature and found that this form of hernia is more often found in women than in men (2 to 1.) More often on the right than on the left. It was found in four cases to be congenital. The pathological anatomy and their origin seemed both indefinitely known.

The intestinal loop finds its way out above the pyriform muscle, and passes along the course of the superior gluteal artery through the incisura ischiatica major, but in some cases it has been known to pass beneath the pyriform muscle, and even one case was reported by Schillbach, in which it passed through the incisura ischatica minor.

In the hernial sacs, aside from the loops of the intestines, the ovary was found in four cases. The hernia was mostly the size of a fist, and the symptoms were of such an undecided nature that diagnosis became quite difficult.—(*Centralb. für Chir.* No. 9–'93.)

Mr. Noopop (grimly): "It didn't wake up at all. It never went to sleep."

ABSTRACTS.

THE COAGULABILITY OF THE BLOOD IN PARTURITION A FACTOR IN OCCURRENCE OF POSTPARTUM HEMORRHAGE.*

T. RIDGWAY BARKER, M. D.

That of all the dangers incident to parturition, post-partum hemorrhage is the most unexpected, sudden and overwhelming, needs scarcely more than mention by the writer. Books, pamphlets and papers innumerable are continually calling our attention to the most radical means of treatment, and yet the death records still find their pages blotted with the names of women who have lost their lives by the failure even of improved methods and measures.

The turbulent stream would seem to have been sounded, and the bars, sunken rocks and shallows accurately located, but for all that shipwreck has occurred. And why?

The ship's course was carefully marked out on the chart; the likelihood of storms was considered, and yet the result was disastrous.

What was it that caused the good ship to go on the rock? Nothing less than the swift, strong, resistless, ungovernable current which we failed to appreciate as we approached the harbor. Had we properly estimated this factor, the results of the voyage would have been far different; and it is to this swift current, metaphorically alluded to, that I wish to call your attention, namely, the blood. In the prevention of the occurrence of post-partum hemorrhage two factors are at work: firstly, tonic uterine contractions and retractions; and, secondly, coagulation of the blood at the orifices of the veins and arteries beneath the decidua serotina.

That a definite relation must exist between these two forces to secure a perfect result is very evident. For if one fail to respond to the normal stimulus, then dangerous hemorrhage will inevitably result.

Fully appreciating the importance of firm coagulation of the blood after delivery as a preventive against hemorrhage, and recognizing the inestimable value of a trusty danger-signal that may be seen afar off, when such a condition does not exist, I have sought for one that might be worthy of credence, and believe I have found it in the blood which escapes from the parturient canal during the second or even earlier stage of labor. Should this fail to coagulate promptly on exposure to the air, then we may take it as a warning that the patient runs no slight risk of post-partum hemorrhage, and every precaution should be taken to guard against a surprise. It is not to be supposed that every female in labor, whose blood does not coagulate with the normal rapidity, is doomed to suffer an attack of post-partum hemorrhage; that would be too sweeping an assertion; but what the writer wishes to declare is, that the danger of post-partum hemorrhage is directly proportionate to the coagulability of the blood and the persistency of uterine muscular contractions.

Further, that the former condition is made manifest during the early stages of labor and may, therefore, be accepted as a danger signal, and precautions taken accordingly. Without firm plugs in the arterial branches and venous sinus we cannot feel satisfied that our patient is free from the risks of post-partum hemorrhage. No matter how great be the coagulative power of the blood, however, it cannot prevent hemorrhage if the ordinary precautions are not taken.

To deliver the fœtus with undue haste, to resort to forcible dilatation of the cervical canal, or to make violent attempts at detachment and expulsion of the placenta, to disregard, in a word, all the fundamental principles underlying the conduct of labor, is to invite hemorrhage in any case. That this easily-acquired knowledge of coagulability of the blood during confinement early in its course can be put to practical advantage needs no confirmation by the writer. It places us on our guard. It warns us to be conservative of the vital forces of the female, and especially so of the blood supply.

*Read before the Obstetrical Society of Philadelphia, February, 1893.

It, moreover, affords us an opportunity to make preparations for the impending danger, and if the obstetrician cannot avert it, at least he can reduce its baneful effects to the minimum.

It is not necessary that all the blood escaping from the birth canal should show this decided tendency to coagulate, for a part of the fluid only may do so, the remainder being so freely diluted with the liquor amnii that such a change is not possible. One clot will indicate its character, and upon this we may place considerable reliance. Of course, though the blood clot firmly, one is not justified in folding his hands when attending a case and saying, "there is no danger from post-partum hemorrhage because you see the blood clots firmly." Not at all! It simply means the female is less likely to suffer in this way than her sister whose blood is so poor and watery that it lacks coagulative power.

The white light may shine out brightly from the switch box, to borrow a phrase from the railroader, notwithstanding the switch is misplaced, if an accident has occurred which renders it inoperative. So with the blood; it may give evidence of containing all its chemical constituents in proper relation and proportion, yet something else may be wrong which prevents its powers being availing. Having seen from the above the close relationship which exists between deteriorated blood and post-partum hemorrhage, the latter in point of fact being the sequence of the former, it remains for us to take measures early in the period of gestation to counteract, by an abundance of fresh air, sunlight and judicious exercise, this degenerative tendency, and so overcome it that our patients, when they are brought to their confinement bed, may be spared the dangers of post-partum hemorrhage.

Nor must the quality and quantity of food taken during this trying period be overlooked, for these matters are no whit less important than those before mentioned. Rich blood insures healthy nerves, which are ever ready to act upon healthy muscles, and these in turn upon the blood vessels.

When we have attained this condition, and associate it with judicious management, post-partum hemorrhage will become a thing of the past.

Consumption Caused by Cows.

"Consumption is the result of drinking cow's milk, and where milk is not used the disease is said not to occur." Rather a sensational statement this when it stands alone and is unqualified. Yet it comes from an authoritive source and is meant to stand alone and unqualified. Dr. Charles A. McQueston, Secretary of the United States Board of Examining Surgeons, and a well-known practicing physician of San Francisco, is the authority.

"I mean exactly what I say; no more, no less. The primary cause of consumption is the drinking of cow's milk. Of course I don't mean that every single case of phthisis is attributed directly to the patient's having imbibed infected cow's milk—though even so strong a statement as that is very nearly true—but I do mean to say that if the American people stopped using cow's milk and butter and cheese made from cow's milk, tubercular consumption would soon disappear.

"Let me put it in another way: In countries where cow's milk is not used tubercular consumption is not known. The scientific world is awakening to this fact, and soon we may expect a more rigid inspection of our daily milk supply. But I must say it is taking us an unconscionably long time to discover this simple truth. And the proof is right at hand and unmistakably plain.

"In China there is no milk consumed and consumption is almost an unknown quantity. Take the steppes of Asiatic Russia. Only goats' and mares' milk is used there. Consequently there is no consumption. Goats and horses are free from this scourge of civilization, and those who use their milk have yet to know the terrors of phthisis. The same condition is, or was until recently, true of the South Sea Islands. No cows, no tubercular disease.

"Take the North American Indians before the white man brought his whisky and his cows among them. They had no word in their language that corresponded to consumption.

"Of course, in our day, doubtless a few cases of phthisis are produced by the person inhaling the dried sputa of a consumptive, and it may be true that some cases are inherited. But the great cause, and the first cause, is the use of cows' milk as a food."—*Med. Brief.*

THE LIBRARY TABLE.

BOOK REVIEWS.

Cheyne-Stokes Respiration. By George Alexander Gibson, M. D., D. Sc., F. R. C. P. E., F. R. S. E., Assistant Physician to the Royal Infirmary, of Edinburgh; Lecturer on the Principles and Practice of Medicine at Minto House; Examiner on Medicine and Clinical Medicine in the University of Glasgow, Edinburgh: Oliver and Boyd, 1892.

In this little monograph, of 130 pages, the author considers the subject under three divisions: Historical, clinical and critical.

In the historical part are given the theories and researches of the various observers from the time of Hippocrates down to the present. The clinical division presents the report of cases, arranged in a definite series, in order to emphasize the difference which they present in the association of phenomena. Tracings are given showing the breathing in various stages and also the conditions of the pulse, respiration and temperature. The conditions underlying the complex of symptoms are considered in the critical chapter and the author sums up as follows: "A careful study of the entire phenomena must lead to the adoption of the view that Cheyne-Stokes breathing is but one of a complex group of associated symptoms. Why there should be such a diversity of phenomena connected with the pulse, eye and mind it is at present impossible to answer. It is only possible at this time to hazard the suggestion that the centres involved in each group of symptoms may be effected singly or collectively. The essential cause of the symptom is without doubt a periodic variation in the functional activity of the automatic centre for respiration. Whether periodic variation depends simply upon the loss of the influence of the higher regulating centres, or whether it is also at the same time the result of diminished vitality, in accordance with some great natural law, it is not at present in our power to decide."

In an appendix the research is brought up to date—the principal part of the work having appeared in articles written by the author for the *Edinburgh Medical Journal.* The work is what one would expect from its author—a scholarly production and an addition to our knowledge of this obsure condition.

The Mastoid Operation. By Samuel Ellsworth Allen, M. D.

The necessity of attacking the mastoid bone for necrotic and carioses condition, resulting from middle ear suppuration, is daily becoming more and more apparent, notwithstanding the fact that its value was recognized as early as the year 1649. Like many other valuable surgical procedures it fell into decline to be again awakened from its lethargy in 1849, though not actively supported until the year 1853, when the well-known periosteal incision of Wilde was published. Since this date current American and European literature has been well sprinkled with successful mastoid surgery. This work of Dr. Allen's is most welcome as its deals in a compact and scholarly manner with the subject from a historical, anatomical, pathological and operative standpoint. Historically it provides us with valuable data. Anatomically, we are furnished landmarks and sections of the temporal bone affording a means of studying the bony structures with comparative readiness. In addition to these sections of the bone the anatomy of the soft parts of the ear is minutely described. Twenty of the one hundred and eleven pages of this book are devoted to a thorough discussion of the pathology of the ear, and after considering carious, necrotic and tuberculous changes we find particular stress placed on the genesis and pathology of cholesteatomatous formations; the author holding the views of Habermann as the most likely explanation, though those of Virchow and other pathologists are also considered. The operative technique as described by Dr Allen is, as he tells us, that advised by a master of aural surgery, Prof. Schwarz. It is a thorough antiseptic method throughout. In mentioning the instruments necessary for the operation the author does not give the trephines or drills any place, considering them entirely uncalled for. His council will hardly meet with universal support, since many operators hold that the operation can be more rapidly performed by first removing with the trephine a button from the outer layer. The first step in the operation is beautifully illustrated by a cut showing a modified Wilde incision; a second showing the field of operation after the soft tissue have been drawn aside.

We are largely indebted to Dr. Allen for the attractive and complete manner in which he has furnished us with this book. While this work is from experience gathered in the European clinics the author cannot be charged with a disregard for American surgeons, since he gives credit to many who may be said to have been among the earliest to report its successes. The book is most valuable and deserves general support and study.

Handbook of the Diagnosis and Treatment of Disease of the Throat, Nose and Naso-Pharynx. By Carl Seiler, M. D., Instructor in Laryngology and Lecturer on Diseases of the Upper Air Passages, in the University of Pennsylvania, etc. Fourth edition, thoroughly revised and greatly enlarged. Illustrated with two lithographic plates, containing ten figures and 107 engravings. 12 mo., 414 pages. Cloth, $2.25. Philadelphia, Lea Brothers & Co., 1893.

This work will be popular with the busy general practitioner both on account of its size and price. It covers all the ground that any general practitioner would be likely to investigate, and does it thoroughly and without circumlocution or ambiguity.

A short chapter is taken up with a history and explanation of the Laryngoscope. As this instrument is the foundation of all throat work such a chapter fills a long felt want. The whole text is well illustrated with excellent cuts which add greatly to its teaching value.

The book is not a mere compilation of dry statements and routine formulæ, but the rationale of each procedure is carefully developed.

It is not burdened with an array of complicated instruments, but simplicity and clearness in detail marks its arrangement. The chapter on Specific Laryngitis is to be commended for both thoroughness and positiveness. For rapid effect he recommends the hypodermatic use of mercury.

Altogether this is a valuable book for the general practitioner, and will be found often available no doubt in the work of the specialist. The publishers have done their work well.

CURRENT LITERATURE REVIEWED.

THE DIETETIC AND HYGIENIC GAZETTE

For April contains three papers. The first, "Hydrotherapy in the Treatment of Nervous and Mental Diseases" by Dr. Frederick Peterson, has already been reviewed in THE MEDICAL AND SURGICAL REPORTER for February 4th, 1893, page 234.

The second article is by Dr. H. Koplik on

The Sterilization of Milk at Low Temperatures

and is taken from the *New York Medical Journal*. The author shows that cow's milk sterilized at temperatures above 100° Celsius, undergoes certain gross and chemical changes which unfit it as an article of food. 85° to 90° Celsius—not above—has, in the writer's hands, proved the most satisfactory and rational temperature to employ for milk which is to be distributed to dispensary patients without control. Such milk is wholesome and unchanged after twenty-four hours, and may keep even in warm and moist weather a week or more without the aid of ice, and, placed in the hands of the most ignorant mothers, will keep for twenty-four hours or more, even if ice is not used. The plan the author adopts in dispensary practice is to give the milk in bottles containing enough for one nursing, a sufficient number of bottlesful being given for twenty-four hours feeding. An important part of the plan is the thorough cleansing and sterilizing of the bottles on their return to the dispensary. The causes of failure in the use of sterilized milk are pointed out and the abstention from milk (even if sterilized) for a short time is pointed out as a most useful adjunct to the treatment of summer complaints where the child's stomach is weak. The paper also includes the rules for household sterilization of milk.

Dr. W. Henry Price presents "A Contribution to the Study of Marasmus," reporting four cases. The paper is continued from a former issue of the journal.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY

For April. [In reviewing the March number of this magazine, we noticed the publication of an article by Dr. Currier in an earlier issue of THE MEDICAL AND SURGICAL REPORTER. The author calls our attention to the fact that, as published in THE REPORTER, the article was an abstract of the original article as it appeared in The Annals, and asks that this note be made. We make it with the addition that THE REPORTER was not aware that the article in question was an abstract, or it would have appeared in the department allotted to abstracts.—Ed.]

Dr. William Warren Potter contributes a paper on

Puerperal Sepsis; its Prevention and Cure.

I. Obstetric engagements once accepted should be fulfilled, no matter how awkardly they fit. Apply the same rule for cleanliness to rich and poor alike. Decline service when this cannot be done. Human life is too precious to jeopardize it by slipshod, half-hearted or indifferent service.

II. The physician should be the model of cleanliness in body and clothing, and should insist upon the observance of similar conditions by all persons in and about the lying-in chamber.

III. The delivery room, whether in hovel or palace, court, alley or avenue, should be simple in its furniture and hangings, and be cleaned with soap, water and whitewash (if possible to use the latter) immediately before occupancy by the puerpera.

IV. The delivery bed should consist of a new tick filled with sweet and clean straw, covered with a blanket, impervious dressing and a folded sheet, with other clean covering to be allowed according to the season. Exceptions to this simple bed should be as few as possible, and in no event should a bed be substituted that has been used by the sick, or that is not beyond even a suspicion of infection.

V. The patient should be specially prepared for delivery by baths and enemata, vaginal douches and clean clothing; and labor should be conducted on the lines of absolute cleanliness, with few digital examinations, and a complete delivery of the secundines.

VI. Lesions of the genital tract should receive careful attention; rents of the perineum should be repaired, and so too, in some instances should tears of the cervix.

VII. Antiseptic solutions containing a germicide should be used for cleaning the hands and instruments of the operator.

Intra-uterine irrigation with sterilized water should be carefully employed after operative midwifery, either manual or instrumental.

VIII. Finally, if sepsis proceed to suppuration and abscess, the abdomen should be opened, pus cavities emptied, irrigation used and drainage established. If the uterus and adnexa become thoroughly infected they should be extirpated.

Dr. Mordecai Price presents the

Report of Cases of Ovariotomy.

CASE I. The patient was supposed to be suffering from a tumor and to be too weak to have anything done for relief. A change of attendants resulted in Dr. Price being called in consultation. She had missed two periods followed by symptoms of miscarriage, and had continued to bleed up to the time of the operation. There was a large tender mass on the left side. The section showed extra-uterine pregnancy ruptured, with the large clot undergoing degeneration. On account of the dense adhesions it was decided to remove only the contents of the sac, wash out and drain. The patient made a slow but perfect recovery.

CASE II. Removal of tubes and ovaries for nodular fibroid disease of the uterus. Recovery.

CASE III. Removal of gonorrhœal pus-tubes. Recovery.

CASE IV. Removal of multilocular ovarian tumor of twelve pounds in weight from a patient 65 years old. Recovery.

CASE V. Removal of double hydrosalpinx. On one side the tumor was as large as the fist, the other half the size. Recovery.

CASE VI. Removal of large pus tube from one side and a diseased and adherent tube on the other. Recovery.

CASE VII. Six weeks before operation the patient had had forcible dilatation of the cervix for sterility. This was followed by a severe attack of inflammation of the left tube, resulting in an abscess which broke into the bowel. At the operation it was impossible to remove all the diseased tube and pus sac on account of the dense adhesions to the bowel and vagina at the site of the fistulous opening. Ten to twelve ounces of pus were discharged through the abdominal opening at the time of the operation. Thorough irrigation and glass drainage. Patient made a good recovery.

CASE VIII. Supra-pubic hysterectomy, with removal of large ovarian growth on the right side, filled with black gelatinous fluid of the consistency of tar, the right tube and ovary much diseased, with an intra-peritoneal cyst in the region of the left kidney, adherent to everything, which was with difficulty removed; no ligature used. In the removal of the uterus it was thought best to ligate the tubes deep down in the pelvis, and apply the nœud at a high level. For six hours after operation there was no perceptible pulse at the wrist. Recovery. The nœud was removed on the ninth day.

Uterine Cancer

is the subject of a paper by Dr. J. M. Baldy. Cancer, he says, has often advanced to an irremediable stage before the historic symptoms of pain, hemorrhage, and bad smelling discharge appear. If, after the menopause has been established, irregular uterine bleeding begins, a strong presumptive evidence of this disease is established, on which we ought to act; if no other cause for it can be found. There is only one treatment for cancer, but it is a question how far it is curative. The treatment of cancer of the interior of the uterus by intra-uterine applications of any kind is simply folly. In his operations he has entirely given up the use of clamps. He makes an opening anteriorly and posteriorly, and ties the broad ligament on both sides with cat-gut, stitches the stumps in the vagina and closes the vaginal vault without drainage. This brings the ligatures into the vagina, where they slough away. It leaves no raw surface; it controls all the vessels, and there is nothing to remove subsequently. It gives none of the theoretical objections of sepsis or hemorrhage following the removal of clamps, although these risks are slight.

Dr. Charles P. Noble reports a case of

Hysterectomy for Soft Myoma of the Uterus.

In the operation he adopted the method of tying off the broad ligaments, amputating the cervix at the level of the vagina and covering the stump with peritoneum, making it extra-peritoneal. He believes that it is wise to sew the peritoneum over the stump in all cases, and that it is good practice to disinfect the cervical canal and to pass gauze through it, in certain cases, to render drainage through the cervical canal more certain. The patient recovered. Dr. Noble also reports a "Case of Ovarian Poly-cyst, removed from a woman suffering from chronic Bright's disease." The patient made a good recovery and he thinks the case offers encouragement to operate for cystoma even in the presence of Bright's disease. In inflammatory disease of the appendages he still believes it unwise to operate; suppression of urine is almost sure to follow. The reason for the better results in tumor cases is plain—removing the tumor removes the pressure from the kidneys and thus tends to assist in restoring their function. Chloroform was used as the anæsthetic because of its supposed advantage over ether in being less irritating to the kidneys.

Dr. Ernest Copeland contributes a paper on

Digital Dilatation of the Pregnant Uterus.

The author finds no successful method of rapid dilatation of the pregnant uterus mentioned in the text books on obstetrics—Barnes' bags being open to the objections that they consume too much time and are generally out of order from deterioration of the rubber, though they most nearly meet the indications. The method he advocates is as follows: After taking all proper antiseptic precautions the patient is anæsthetized and placed in the dorsal position. The index finger of the operators's right hand is inserted in the cervix and when the os is sufficiently dilated to admit two fingers the

index finger of the left hand is also introduced and the uterus drawn down. It is often of undoubted benefit to have pressure made from above by the hands of an assistant. The fingers are now rotated from left to right and from right to left, the finger of each hand completing half a circle, bringing uniform pressure to bear successively on each portion of the cervix; as the os dilates other fingers are introduced until three fingers of each hand are used. He emphasizes the fact that this is not simply a stretching process, but uniform distribution of force successively to each portion of the cervix. When the uterus is sufficiently dilated the case is conducted as an ordinary labor. He has practiced this method of dilatation for several years and has not found a case that could not be readily dilated. His experience is that there is no more danger of lacerating the tissue than in a labor where one must resort to instruments or turning. The method is particularly applicable to cases of eclampsia where delivery must be accomplished quickly. The advantages of the method are:

I. The cervix can be dilated more rapidly than by any other method.

II. The means of dilating are always with one, with no appliances to get out of order.

III. On account of the uniform distribution of force, laceration is scarcely more likely to occur than in a normal dilatation.

The author includes in his paper the reports of a number of cases in which the method was applied with success.

Dr. L. S. McMurtry contributes a paper on

Abdominal Hysterectomy.

There are practically three methods, he says, of treating the pedicle: 1. To fix it in the lower angle of the parietal incision. 2. To provide against hemorrhage by ligature and suturing and drop it as in ovariotomy. 3. To completely excise the cervix. In his own cases, seven in number, he has used the nœud exclusively. All his cases have recovered. The great dangers to keep in mind in abdominal hysterectomy, besides sepsis, are shock and hemorrhage. Injury to the bladder and ureters are ever present dangers during operation. Everything which prolongs anæsthesia and protracts the operation tends to beget shock. The operation with the nœud is the easiest to execute and requires less time; hence shock is reduced to a minimum. When the nœud is properly applied to a reduced pedicle, it is as surgical and elegant as any operation whatever. Scientifically considered, the nœud is nothing less than a wire ligature adjusted under absolute control, and guaranteeing safety against hemorrhage. The pedicle must often be reduced and no one who has not mastered the making of a pedicle by deperitonization and reduction can do justice to the practical application of the nœud in hysterectomy. The method is applicable to all sizes of tumors, and is readily applied in those cases where the tumor rises out of the pelvis and lifts with it the pelvic peritoneum and broad ligaments, and commends itself to confidence by its results.

In the Department of Pædiatry, Dr. H. Augustus Wilson contributes a paper on "The prevention of Idiopathic Rotary Lateral Curvatures of the Spine." All forms of shoulder braces are condemned and proper gymnastic exercising of the whole muscular system advocated. Training in correct carriage, such as that given the cadet at West Point and Annapolis, is also recommended. The article is illustrated with many photographs explanatory of the various points of the paper.

LIPPINCOT'S MAGIZINE

For May, 1893. The complete novel in the May number of Lippincott's is from the facile and well-tried pen of Rosa Nouchette Carey. Its title is "Mrs. Romney." The third in the series of Lippincott's notable stories, "A Pastel," by Cornelia Kane Rathbone, is a touching sketch of wasted loyalty and disappointed hope. It is illustrated throughout. James Fox furnishes a full and glowing account of "New St. Louis," illustrated with cuts of a dozen of the huge buildings which have lately risen in that thriving and progressive city. John Bunting traces the origin and history of "The Society of the Cincinnati," with the violent objections which were raised in its early days against its supposed aristocratic character and dangerous tendency. This article also is illustrated. Mrs. Gertrude Atherton supplies a short but appreciative account of the American sculptress, Kuhne Beveridge, with a cut of her most notable work, "The Sprinter." Professor L. M. Haupt has a brief article on "Colonel Pope and Good Roads." M. Crofton, in "Men of the Day," gives sketches of William Morris, the poet, Archbishop Satolli and Secretary of War, Lamont. The poetry of the number is by Louise Chandler Moulton, Dora Read Goodale, Charlotte Pendleton and Arthur D. F. Randolph.

Deaths Under Anæsthetics.

Gurlt reported to the last Surgical Congress at Berlin, the following statistics of deaths under anæsthetics. They are made up from the observations of 62 operators, who anæsthetized 109, 196 persons, with 39 fatal results, showing one death to 2,800 narcoses. The following were the anæsthetics used:

Chloroform, - -	94,123	narcoses,	36 deaths
Ether, - - - - -	9,431	"	no deaths
Ether and choloform,	2,891	"	1 death
Ether and alcohol,	1,381	"	no deaths
Bromoform with ethyl bromide,	2,151	"	1 death
Pental, - - - - -	210	"	1 death

In 2,913 cases the narcosis lasted over an hour; in an operation for utero-vaginal fistula, 4½ hours; in a case of tetanus, 9 hours. In 25 cases, of which post-mortem examinations were made, cardiac diseases were found. The author urges careful examination of the heart before administering chloroform—*Cond. Ext.*

PERISCOPE.

MEDICINE.

Toxicity of Urine of Patients with Suppurative Affections.

Nanotti and Baciocchi (*Rif. Med.*, 1892) have sought to ascertain whether in all suppurative processes, from the most trival to the most severe, the pyogenic organisms are eliminated by the kidneys. As the result of their labors they affirm:

1. That in every suppurative process, no matter how limited, even if there be absence of any general reaction, the microbes are eliminated by the kidneys without producing any appreciable renal lesion.
2. That pyogenic organisms eliminated in this way are still possessed of considerable virulence.
3. That the urine of such patients has a toxicity distinctly greater than that of normal urine.
4. That such urine is capable of producing wound infection.

That practical deductions to be drawn from these results are as follows: First, in suppurative affections to encourage elimination by the kidney, choosing, however, those diuretics which do not greatly affect the renal circulation. Secondly, the infective nature of the urine is a sufficient indication of the desirability of disposing of this efficiently.—*British Med. Journal.*

Salicylates in Treatment of Pleurisy with Effusion.

Dr. George Dock speaks highly of this method (Huber's) and concludes a paper on the subject (*Ther. Gaz.*):

1. Salicylic acid and its salts are among the most effectual agents in the treatment of pleurisy with effusion.
2. In effective doses the remedy is harmless, and with proper selection of the preparation, and care in administration, causes little or no discomfort to the patient.
3. Salicylates act most promptly in pleurisies with serous effusion of recent origin or of long standing, but they are efficient in simple dry pleurisy, and often act favorably in secondary pleurisy.
4. There is no evidence that they are useful in suppurative cases.
5. The drug acts as a diuretic, but may have an effect on the pathological process, or on the cause of the disease.
6. Salicylates have a more marked action in pleurisy than have the diuretics commonly so called.
7. "The duration of the treatment with salicylic preparations is less than with diuretics, common salt, or roborant medication" (Eugster).
8. The remedy can be used at the earliest period, and favorably affects all symptoms.
9. The drug may be given in the form of the acid, or any of its salts, in doses of a drachm of the former, or one or two drachms of a salt daily. In ordinary cases it is not necessary to give the larger doses, and sixty to ninety grains of sodium salicylate or salol daily may be considered full beginning doses, to be diminished one third or one-half after the effect is manifest.
10. The ordinary precautions must be observed in giving the drugs, and during their administration the total amount of urine should be measured daily.

Physiological Action of Massage upon Human Muscle.

In the *Arch. Italiennes de Biologie*, Maggiore's experiments with Mosso's ergograph lead him to the following conclusions:

1. Massage applied to muscle at rest increases its existence to fatigue, and modifies and delays fatigue proper.
2. In certain cases the good effects of massage are in proportion to the length of time that it is given.
3. Massage prevents in muscles the accumulation of fatigue-products due to work that is too closely consecutive.
4. Percussion and rubbing are inferior to kneading and to mixed massage; that is, to the alternate application of these three methods.
5. In muscles weakened by fasting, massage increases resistance to the effects of work.
6. Upon muscles fatigued or weakened by general causes, as forced marching, watching, brain-work, massage exercises a restorative action.
7. Massage has no good effect whatever upon muscles in which the circulation of the blood is suppressed.

OBSTETRICS.

Vomiting in Pregnancy.

In closing a paper on this subject (*Boston Med. and Surg. Jour.*) Dr. R. A. Kingman offers the following brief suggestions:

Vomiting of pregnancy means suffering and distress which you are bound to relieve.

There is no difference save in degree between the so-called "physiological vomiting" and "pernicious vomiting."

Simple "morning sickness" may pass into "incœrcible vomiting" and prove fatal.

The vomiting of pregnancy results usually from some uterine displacement or other local cause which interferes with the normal expansion and development of the uterus.

This local cause is in a majority of the cases an anteflexion and partial prolapse of the uterus with induration or the tissues in the cervical angle.

To cure the vomiting it is necessary to remove the local cause.

This done, morning sickness need no longer be an essential part of pregnancy.

Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co.

Phenacetine-Bayer

ANTIPYRETIC and ANALGESIC; Prompt, safe and effective in Fever, Influenza, Rheumatism, Neuralgia, Pneumonia, Cephalalgia and all forms of pain.

Phenacetine is given in doses of 2½ to 10 grains, 3 or 4 times daily. It does not depress the heart.

Phenacetine is supplied in ounces, also in tablets and pills, alone and with Salophen, Sulfonal, etc.

Sulfonal-Bayer

HYPNOTIC and SEDATIVE; Indicated in all the Insomnias including those of insanity and the Neuroses; Causes no nervous or gastric disturbances. Must be given as directed.

The dose of Sulfonal varies from 15 to 45 grains; It should be given an hour or two before bedtime.

Sulfonal is supplied in ounces, tablets and pills; also in tablets in combination with Phenacetine.

Other Farbenfabriken Products:

Salophen, Trional, Aristol, Losophan, Piperazine-Bayer, Europhen.

New descriptive Pamphlets on these Preparations mailed by

W. H. Schieffelin & Co., New York.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

NO WAX

Is used in our **Hollow Suppositories.** Made from purest **Butter of Cocoa only,** which **melts** at the temperature of the **body.** Can be filled with any medicine. Anal, Nasal, Urethral, Cystic, Vaginal, and Intra-Uterine sizes.

Also, Ricord's Solid Suppositories for Gonorrhœa, and Nelaton's Solid Suppositories for Constipation and Piles. Samples sent Free on application and mention of this paper.

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

ORIGINAL ARTICLES.

RAPID OPERATIVE PROCEDURE AS A MEANS OF REDUCING THE MORTALITY IN ABDOMINAL AND PELVIC SURGERY.*

A. H. CORDIER, M. D.,† Kansas City, Mo.

For some time I have turned my attention and devoted my time and study to intra-abdominal and pelvic surgical diseases; a sequence of this special work has been to accept the truths taught by others of experience, to follow the dictates of my own convictions and to endeavor to carry out the good, to find the flaws in the defective and avoid the same, and to improve the technique where it is possible.

The surgery of the pelvic and abdominal organs presents many features characteristic to this locality. The structures in these great cavities are peculiarly sensitive to all surgical manipulations and outside influences, and many of the organs being essential to life it behooves the surgeon to be exact in his deductions, accurate in mechanical skill, quick and decisive in its execution. The dangers here are many, and extremely rapid and fatal are their destructive processes when once initiated.

The carelessness, want of clean-cut ideas and absence of a conscientiousness of the great responsibility hovering over the surgeon doing this great work is only too often responsible for much suffering and loss of many lives, that under more favorable circumstances or even with the same surroundings, in the hands of some one who recognizes the cardinal principles underlying this work and carries them out in detail, would recover and have a long, useful and comfortable existence.

I propose in this short article to deal with the important question of the time occupied in doing this class of surgery, endeavoring to show the necessity for rapid work, how it is done and why it is so essential to success. In looking over the literature to which I have access, I have been unable to find a single article written upon this important topic; I am aware of the fact that in all text-books on surgery an occasional injunction is offered to the surgeon to do his work quickly, but the various and special reasons why the time of performing an abdominal operation should be reduced to a minimum has not been given. Before anæsthetics rapid work was advocated, but with the advent of chloroform and the acquisition of the Esmarch bandage as aids to the surgeon the important question was, in part, lost sight of and deliberate "chronic surgery" carried out. Most surgeons present, no doubt, with rare exceptions, on hearing my article up to this point will say: "I always do my work as rapidly as I can." But just wait a moment and see if you do. Examine the preparation of the patient and the surroundings, instruments, the position and allotted duty of your assistants, nurses, anæsthetizer and visitors or those

*Read before the Western Association of Obstetricians and Gynecologists, at Kansas City, Mo., Dec. 27th, 1892.

†Member of American Medical Association of Obstetricians and Gynecologists; Corresponding Member of Obstetrical Society of Philadelphia, etc., etc.

witnessing the operation, follow your manœuvers all through the operation and see if at one or more points you cannot reduce the time of doing your work. I am sure no one will disagree with me, when I say, that an operation cannot be too quickly performed, if skillfully executed, and that an operation can be done just as well, yes better, if done quickly, than if much valuable time is needlessly squandered in dancing about aimlessly. Good surgery does not countenance reckless and undecisive haste, but good surgery does demand clean cut views in quickly recognizing unlooked for complications, rapid and good execution in dealing with the same.

The preparation of the patient for an abdominal operation is an important time-saving procedure, the details of which it will be necessary to vary to meet the indications in individual cases.

The contents of the bowels should be kept soluble for a few days preceeding the day set for the operation, and a saline cathartic administered the day before and an enema given to empty the colon of fæces and gas. This will be found to reduce the time of performing the operation; the intestines being empty will retract, if not adherent, toward the diaphragm out of your way as soon as the incision opens the peritoneum. This preliminary emptying of the intestines reduces the dangers incident to an accidental or unavoidable injury to a gut and minimizes the time in its reparation, since it is much easier and can be done better and quicker with this canal empty.

It is better to have your patient's bowels emptied before being placed on the operating table, for it takes up valuable time and prolongs the anæsthesia, to remove soiled blankets, etc., etc., make the additional or new preparations, made necessary by the large involuntary intestinal movements after your patient is anæsthetized. Have the patient empty the bladder; if it is necessary that a fluid be in this viscus, inject a mild antiseptic liquid, it will require less care and time in preventing its escape or removing this liquid should any of the liquid escape into the peritoneal cavity. The preparatory bath should not be neglected. The final washing is to be done by the second assistant after the patient is placed on the operating table, and the field of operation prepared that the surgeon may have aseptic surroundings to begin his work in; by the assistant doing this part of the work it saves the time the surgeon would occupy in "scrubbing up," should he do the final cleansing of the field of operation. Every moment saved this way reduces the time of anæsthesia sixty seconds.

Preparation of instruments is an important part, the technique of which should be scrupously carried out in its fullest detail. Have within quick and easy access all instruments necessary to performing operation within the peritoneum, to meet any complication liable to be found in this locality. Have in your trays only those you think you will need, if in doubt as to what you may need, place the "doubtful" in a separate tray. Educate yourself to the use of a few instruments and it will be a surprise to others to see with what dexterity you use them and to what a wide range you skillfully apply them. A large tray filled with a mixture of instruments foreign to the field of operation, suggests to the mind of the student of surgical simplicity, and at same time exactness, a want of discrimination and judgement on the part of the surgeon. Three pairs of scissors, three or four scalpels, etc. (in duplicate) are too many to do exact work with at same time on one patient. Have your needles threaded and placed so that they will not be tangled when you are ready to use them. I have seen much time occupied by the surgeon and assistants in threading and rethreading one or two needles while the same were being used over and over again in closing an abdominal or intestinal wound.

Have as few assistants as it is possible to get along with and place them where they can be of the most service to you and as little injury to the patient as possible. Your first assistant should be an operator of ability *and not* a first course student or even a nurse with less experience.

The steps of the operation should be thoroughly understood by the assistant that your movements may be anticipated by his endeavors to assist you. The wrapping of the patient's limbs in a flannel blanket should be done by the nurse as soon as the anæsthetic is administered or begun.

The anæsthetizer is indeed a very important personage in an abdominal operation and too much stress cannot be placed

upon the responsibility his position places upon him. He is expected to do his work quickly yet safely, taking due precaution to ward off any of the accidents that occasionally attends the use of these indispensible agents. He must keep his patient evenly under the influence of the drug, using only the necessary amount to do this. Vomiting, swallowing false teeth, cleft palate plates, gum, etc., etc., interrupt the surgeon in his work and takes time to do that which should have been avoided. The use of hypodermics of strychnia, and other restoratives must be resorted to in some instances and should be carried out by the physician giving the ether or chloroform. In patients with any pulmonary disease, we find bad subjects for anæsthetics and the time must be reduced to as short a period as possible. The time will come when the surgeon, who occupies three hours doing an operation and his patient dies, (they will often die from three hours of anæsthesia alone) that surgeon will be called upon by an officer of the law to defend himself against the charges of manslaughter. I trust this may never occur.

Any operation of long duration within the peritoneal cavity with consequent exposure and handling of the viscera is attended with a condition of profound and dangerous shock. This added to the depression of the vital functions from the anæsthetic is a danger to be avoided or reduced to the least risk by doing the work quickly.

In extra-uterine pregnancy with rupture and large intra-peritoneal hemorrhage the patient is in a condition of profound shock and acute anæmia, either of which must not be intensified by any prolonged surgical procedure, yet a resort to surgery offers in most cases the only hopes of saving the patient. As soon as the abdomen is opened and the pent up blood finds an exit, the hemorrhage at the site of rupture starts up anew with alarming rapidity. Your work here must be quick and decisive or the woman will die from a hemorrhage, probably started up afresh by your slow surgery.

Case I. *Extra-Uterine Pregnancy.* This lady eleven weeks before I saw her, had her last menstrual period. She was nauseated for a few weeks, no escape of decidual membranes (?). At the tenth week had a severe pain in right iliac region, accompanied by a "giving way feeling," with considerable weakness lasting a few hours only; no physician was called. A week later the pain in the same locality returned with increased intensity and of longer duration accompanied by alarming symptoms of profound shock and acute anæmia. A physician was quickly called who wired me to "come at once prepared to operate on a case of extra-uterine pregnancy." I saw the patient eight or ten hours after the rupture took place and the hemorrhage began. She was indeed in an alarming and dangerous condition; she had bled until her pulse was almost imperceptable and her lips were like those of an unpainted wax figure. Her whole aspect was one pointing to an early death if not quickly brought out of her precarious condition. While I was hurriedly getting my instruments in readiness, the water was being boiled and hypodermics of strychnia were given. As soon as all arrangements were perfected the ether was administered, only a small amount being necessary. The operation revealed a ruptured tubal pregnancy at about the twelfth week. Her abdomen was full of blood. The "specimen" was quickly found, a good stout ligature thrown around it and the hemorrhage immediately ceased. Hot water irrigation improved her condition, but even this was carried out quickly; much of the irrigation fluid was allowed to remain to be absorbed by the thirsty blood vessels and absorbents, the remainder to be removed through the drainage tube. Time of operation twenty-two minutes. A longer operation would have cost the patient her life.

In operating on patients whose heart and kidneys are not in a healthy condition, we have an indication for short anæsthesia.

Case II. *Double Ovariotomy; Recovery.* This lady, aged 38, has not walked a block for over a year; valvular heart lesions; pulse 120 to 130, intermittent and very weak. Took the anæsthetic very badly. Cystoma of left ovary size of goose egg, with both Fallopian tubes containing pus. *Every thing in readiness before anæsthetia was begun.* Adhesions firm on left side. Time of entire operation including tying of sutures, thirteen minutes. To have been slow in finishing this operation, with the necessary prolongation of

the anæsthetic would have been at the expense of entailing much danger to my patient's safety. The operation was performed just as well as though I had occupied a half hour longer in making my preparations after the patient was on the table, or had danced about in the pelvis aimlessly twenty or thirty minutes, or had used only one needle and stopped to rethread this one after each suture was introduced.

In patients with high temperatures where the eliminative functions of the skin and kidneys are in abeyance, any long anæsthesia and surgical operation is attended with much hazzard.

In performing a Cæsarean or Porro operation we take an additional human being into our hands, the life which our endeavors should be so directed as to save. Any illy directed or tardy manipulations here may be at the expense of both mother and child, and thereby bring approbrium to this God-sent life saving precedure. To anticipate complications and at same time expediate your work, do that part of the operation attended with little danger quickly, do not occupy twenty minutes (as I have seen) in making an abdominal incision that should be made in as many seconds. Make a small incision but not so small that you are retarded in your work by narrowness of the abdominal opening. Give yourself room.

In intestinal work the judgment of the surgeon will often be called upon to settle the question as to whether he shall do an ideal operation or content himself by a temporary procedure until his patient is in a better physical state to undergo a longer and more radical operation. The answer to the question, "Will the patient stand the longer or more radical operation?" should in the judgment of the surgeon map out his course in the case. In some forms of intestinal obstruction a resort to a quick enterotomy will be a safer step than a prolonged search for the source, and endeavor to remove the cause of the obstruction.

In appendicitis with an inflammatory diaphragm separating the abscess cavity containing the diseased appendix, in a patient suffering from pronounced systemic infection, it is better surgery to simply cut down upon the abscess quickly, let out the pus, irrigate and drain, than to delay the time of operation, prolong the anæsthesia, and subject the patient to the risk of shock, a diffused septic peritonitis and death. This is not ideal surgery but the patient will get well often with this short and quick method of treating these cases.

The close proximity of fetid pus to the peritoneum in suppurative appendicitis produces very early unusual depression.

This is noticed by the shock accompanying or following the anæsthesia and even a simple incision, here "chronic surgery" would kill the patient.

Case III. *Appendicitis, with Perforation, Abscess, Operation, Recovery.* This patient was 19 years old. Gave a history of an attack of appendicitis occurring a year ago—I saw the case in the second week of the present attack—found him in following condition: Pulse 55; temperature 96½° F.; features pinched; extremities cold, great beads of cold perspiration standing on the forehead; hiccough and vomiting; bowels constipated; a well-marked mass the size of the fist with marked tenderness existed in region of appendix. His condition in fact was of the most alarming character, the outlook for improvement by an operation was certainly most discouraging; without an operation death was sure to quickly close the scene. All preparations being in readiness the anæsthetic was administered and the operation quickly performed. The entire time of *anaesthesia* being only eighteen minutes. I cut down upon the lower border of the mass, opened it up, found a perforation of the appendix at its junction with the cæcum. The appendix was bound down by the mass of the inflammatory breastwork. The appendix was not removed. A cherry stone was found lying loose in the abscess cavity. A rubber and iodoform gauze drain were introduced and much of the wound in the parietes left open. While this was not ideal surgery, my patient recovered from the *operation* and probably the mass will be absorbed; the appendix atrophy. If this favorable termination does not take place and he is threatened with a recurrence of his trouble, he can have another operation for the removal of the appendix when his condition is such as to stand this more prolonged procedure.

There are many more important and good reasons why we should be quick in our abdominal work, but I trust I have

mentioned enough to impress anew on the minds of those present the necessity for rapid work and that this short paper may be the means of eliciting a discussion along this line, that will bring out new features, indications or reasons why the time of performing an abdominal operation should be reduced to the minimum.

CLINICAL LECTURES.

CLINICAL OBSERVATIONS IN NEW YORK.

W. H. LINK, A. M., M. D.

On Tuesday afternoon Dr. Thomas Addis Emmet operated ar the Women's Hospital. He did his perineal operation on one patient and amputated the hypertrophied and elongated cervix on another.

Both these operations were done in an ideal manner and the explanation of each step, the reason upon which it was founded and from which it was developed, were elaborated and made clear by impromptu drawings on the black-board. Dr. Emmet laid great stress on the disastrous effects of cicatrices in erectile tissue. All scar tissue he removes and mucous membrane is sewed to mucous membrane, thus restoring parts as nearly as possible to their normal condition. He believes that many women are brought up in a mad-house from the neglect of lesions that any one might readily repair who would give the principles of good plastic surgery a little attention. But now every one who graduated wanted to take out the uterus or do some other work inside the belly. The result was that such things as rectocele, or cystocele, or lacerated cervix, or complete sphincter-tears, with their attending miseries, were completely overlooked or entirely ignored. Another result of the great abdominal craze was, that plastic work was so absolutely pushed aside that good plastic surgeons were becoming scarce. The doctrines that he has been setting forth for thirty years, the operations that he has been perfecting during the same time were replaced by everybody's modification, while men were daily found claiming to do a *modified* Emmet's operation who did not even *understand* the real operation when they saw it done by its author himself. He claims that there are very few men in New York that either understand or do his operation for restoration of the pelvic floor. From some attempts we saw made to do a "*modified*" Emmet we are satisfied that the old man is correct. He claimed that, of men outside of New York who were exemplifying his works and its underlying principles, Dr. Joseph Price, of Philadelphia, and Dr. Howard A. Kelley, of Baltimore, did it the best.

One feels, while listening to Emmet talk, that he is in the presence of a medical and surgical sage. In his case speech is golden and the words and precepts that have grown out of almost a third of a century of toil and devotion to his chosen specialty, fall from his lips in an endless stream. He is as fresh in thought, as rich in language and as fertile in illustration as though in the prime of life; his physical vigor is surprising to those who have known of him so long, while his heart is as young and his courtesy as chivalaric as in days long ago in old Virginia. He is a grand old man and it will be an admitted fact some day that Emmet, Sims and McDowel are America's three great masters to whom the medical world can point with a just pride long after most others are forgotten.

Another of New York's brilliant and able men is Dr. Wm. M. Polk. The two things that just now attract the attention of the vistor to him are his conservative work on the ovaries and his treatment of endometritis and some forms of tubal disease by curettement, irrigation and iodoform gauze-packing of the uterus.

He does not believe in removing an ovary unless it is so hopelessly diseased that none of it can be left with safety. We saw him remove a dermoid ovary from the left side of a patient while on the other side he split the remaining ovary al-

most to its base, punctured and emptied several collections of fluid both from the internal and external surface, then sewed up the incision in the body of the ovary with a continuous Lambert suture of catgut and dropped it back into the pelvis. He did this for two reasons, he said: the woman desired to become a mother; and the ovary predominated the individual and is as essential to the preservation of those finer and more delicate shades of character which serve to differentiate woman from the opposite sex, as the testicles are to preserve the masculine character of the man. He claims that most disease of the appendages has its origin in an endometritis. That the endometritis often exists with healthy tubes and ovaries above. That a careful curettage and gauze pack promptly cures the endometritis. That when the disease of the tubes is comparatively recent and the tubal opening at the uterine end is patulous, a curettage of the uterine canal with gauze packing drains the tube and shutting of the original nidus and origin of the disease, most frequently cures the pyosalpinx. That, if it fails to cure, the endometritis is cured and abdominal section may be still resorted to for the cure of the pelvic trouble. But in old cases of suppurative pelvic disease he does not recommend the gauze packing unless preceeded by a section and it is then done only for the cure of the uterine disease and to hasten the convalescence. He drains some pus cases through the vagina by incising the vaginal vault, but this he recommends only as a temporizing measure in those cases of long standing so reduced by sepsis that a section would prove fatal. After draining through the vagina and giving such relief that their strength is partially restored and their condition improved, he makes a section and removes the diseased structures. He is a very cool, deliberate and graceful operator. His technique is perfect, his work thorough and radical except where modified by his theories.

He is the soul of courtesy, and he impresses one as a masterful man, who does not have to cross the ocean to have any questions settled for him. He talks, looks, acts and works like an investigator. He does not appear as if he feared to assume responsibility, or to settle a question for himself by the light of his own experience. He is the son of Bishop and General Leonidas Polk, and he undoubtedly has inherited more of the general than the bishop in his father's character; for he has the quick decisiveness of the military man, and his personal bearing and precision of movement all betray the military element, which is his both by inheritance and early training.

No one looking for good abdominal surgery ought to leave New York without seeing Polk.

Quinine Pill-Mass—A Catch Prescription.

APOTHEKER, St. Louis.—Here is a prescription handed me to be filled, by a young M. D. just back from a few months' stay in the old country. How would you fill it?

℞ Quinine sulphatis.....grs. xv.
Acidi sulphur. dil.....q. s.
Mix and divide into six pills.

Don't you think the young doctor had better go back to Germany again for another semester or two?

The prescription is all right, as you will find if you mix the ingredients in a hot porcelain capsule. Add about five minims of the acid, and in a short time you will have a beautiful mass. This very question was some years ago the occasion of the appointment of a pharmaceutical commission in either Austria or Germany, we forget which. A certain apothecary who had accidentally discovered the reaction, had a physician friend to write the prescription and send it to his rivals around town, all of whom declared that the pills could not be put up without the use of other ingredients. Apothecary No. 1 thereupon put up the prescription, and was roundly denounced by the other apothecaries as a fraud. The matter got into the local journals and came to the attention of the authorities, who thereupon appointed a commission of three experts to investigate. The commission differed; one of these declared it was impossible to make the pills without the addition of other ingredients. Another thought it possible, but very difficult, while the third experimented a little and solved the matter. It is highly probable that your young doctor had read of the matter (as considerable litigation grew out of it) and gave you the prescription as a puzzle.—*Nat. Drug.*

COMMUNICATIONS.

SOME OBSERVATIONS ON THE THERAPEUTIC TREATMENT OF UTERINE FIBROIDS WITH REPORT OF CASES.*

CHAS. W. ADAMS, A. M., M. D.†

In presenting my subject: "Some observations on the Therapeutic Treatment of Uterine Fibroids with a report of Cases," I shall beg your indulgence and assume on your part a knowledge of many facts, which I have not the time nor opporturnity even to touch upon. The subject is so broad, that it would be useless to take it up in its entirety, within the limits of a single article, and hence I may say that my paper is simply the record of an experiment carried out in a certain direction, and as such I give you the results of my experience.

The cases which I have observed are essentially clinical in their nature, taken from my Women's Clinic during the past two years. From the entire number seen, I shall select for report only those, which, from the length of time they were under observation, can give some positive data, by means of which we may come to a definite conclusion.

Before entering upon their consideration it may be well to make a few preliminary observations, in order that there may be a proper understanding of the cases to be reported.

I will start with this as an axiom, that so long as fibroid tumors of the uterus exist, women should be given the benefit of every method of treatment and operation combined with judicious selection. If this be admitted, it follows that true conservatism demands that every method of cure or treatment must be recognized and understood and no one method used or depended on to the exclusion of every other. I may be pardoned in making this statement, since you as well as I know that it is the tendency for the physician to select one method, and decry the value or benefit of every other, save that which he may follow.

While therefore in my paper I shall report the benefits of but one method of treatment, I do not wish to be understood as using that alone. In fact, according to indications, I should use any one of all methods which the experience of the profession has shown to be of use in the treatment of uterine fibroids.

I have purposely confined my observation to my public clinic, because the cases are matters of record, of access to every one and have been under the eye of not only myself but that of other observers. Many of the cases were under the observations of Physicians during the "Practitioners Course" last spring and were weekly seen and examined, and the effect and course of treatment observed and studied.

Briefly then, I am speaking of fibrous tumors of the uterus or more correctly myo-fibromata—pathological growths—composed of connective and muscular tissue, the one or the other tissue predominating in different tumors. The prominent symptoms for which the patient may present herself for treatment and for which relief is sought by medicine or operation, are menorrhagia, metrorrhagia, pain through the pelvis, profuse leucorrhœa, watery discharge, pressure symptoms, etc. In considering therefore the means of relief or cure of any given case of myo-fibroma which may come under observation, we should bear in mind not only the conditions present, the symptoms for which relief is sought, but the prognosis, course, duration and termination as well. If the case were one of ovarian tumor, which would sooner or later endanger the life of the patient, no one would deny that the end sought should be operation and removal of the growth as soon as it was recognized. But in the case of a myo-fibroma, I think there is every reason to act with more caution. As long as there are no urgent symptoms or the tumor did not interfere with the vital condition or nutrition of the patient, there would be every reason to act with

*Read before the Western Association of Obstetricians and Gynecologists.

†Prof. of Gynecology in University Medical College, Kansas City, Mo.

the utmost conservatism. This seems to be the consensus of opinion of the majority of thinkers and workers in our field, and whatever may be the opinion of individuals, it should be entitled to consideration.

I here call your attention to these facts also, which I have taken into consideration in making these statements. I mean the disputed points of benign growths taking on malignancy, also the tendency to cessation of growth after the menopause has occurred as well as other reasons which might argue for the operation of removal of such growths in every case. The advocates of the different methods of the management of a myo-fibroma, have so thoroughly laid their methods and results before the profession that I need not mention them. At present those who favor operation are the most aggressive and seem to have the ear of the profession. Yet while the results of operation have been so safe and sure in the hands of a few, I cannot bring myself to believe that it is the only and final resort. I cannot but believe that there will and must always be a necessity for a proper and judicious selection of some one of all methods used, governed always by the indications of a given case.

It was with these views in mind, that I have carried out a series of therapeutic experiments on cases of myo-fibromata during the past two years, the result of which I shall give in the following reports. I regret only that they do not embrace a larger number and extend over a wider range of cases.

The number of patients seen was sixteen—fifteen colored and one white. The oldest was aged 45—the youngest 29—the average was 37 years. In the sixteen seen, three had no children but had had from one to three miscarriages. Two had children but no miscarriages. Nine had neither children nor miscarriages. In arriving at a conclusion as to the cause of uterine fibroids in my cases, I would say that race, age and nuliparity play a large part in their production. I may also state in this connection that only one of the sixteen was of the class of myo-fibiocystic tumors.

The treatment carried out in every case was the same, viz.:

℞ Fl. Ext. Ergotæ
Fl. Ext. Salix Nig. ..... aa 5ss.
M
Sig. To be taken three times daily.

The reason for the selection of this combination of drugs was mainly theoretical, but practical experience has certainly demonstrated its usefulness in certain cases as a scrutiny of the cases to be reported will show. The ergot is useful from its contractile effect upon the muscular tissue of the uterus as well as on the myo-fibroma within it or connected therewith. The action of this drug in this connection needs no further mention. The salix niger as a sexual sedative, a repressor of passive hemorrhage and chronic mucous discharges, a diuretic as well as a mild tonic has acted well in every case in which it was indicated. In its combination with the ergot the mixture has been borne for months continuously in every case without any unpleasant effects.

With these explanatory remarks, I may now report the cases which came under observation and which were treated according to the above formula. I have selected only those who, from the length of time they were under observation and on the same treatment, will furnish undoubted data from which to come to a conclusion. I regret that my cases are not more complete as regards history and course. You will however bear in mind that I was dealing with an ignorant class in many of whom it was difficult to ascertain even their correct age. I did the best possible under the circumstances.

Case I. Mrs. C——, colored; married; age 43; never pregnant; came under observation January 12, 1891. Nothing irregular with menstruation; no discharge from the vagina.

Symptoms complained of were initability of the bladder and rectum, pain and dragging sensation in the abdomen and pelvis, uterine tenesmus. General health fairly good. Examination shows large, smooth, round and solid growth in abdominal cavity reaching above the umbilicus, but little movable, due perhaps, to its size. The tumor was made out as springing from the posterior side of the fundus of the uterus, which was crowded down under and against the arch of the pubis. Its size and depth could not be well made out.

Diagnosis—Myo-fibroma.—Patient was placed on:

℞ Fl. ext. Ergotae } .....aa3ss.
Fl. ext. Salix Nig. }

to be taken three times daily. Ordered

to report for observation once a week. The patient was kept on this treatment steadily up to Dec. 3, 1891. During this course of treatment I find at periods of three and four weeks interval the following notes in my clinical record book: Tumor smaller and freely movable. Tumor still smaller; freely movable and all signs of pressure and pain in abdomen gone.

On Dec. 3, 1891, when the laparotomy was performed for its removal, the growth was about the size of a large orange, freely movable without adhesions, and could clearly be made as springing by a thick, fleshy pedicle from fundus of uterus.

Case II. Mrs. K——, colored; married; age 35; no children; came under observation June 26, 1891.

Symptoms.—Menstruation regular but painful; excessive flow until three months ago; complains of lancinating pains in abdomen and pelvis. Vesical and rectal irritation. Is almost bedridden, being brought to clinic in a hack.

Examination.—The growths, which were noticed some years ago, are now nodular and multiple, completely fill the abdomen extending up to ensiform cartilage.

No clear diagnosis could be made out on account of the size of the tumor. The only fact which seemed certain was that we had to deal with an enormous myo-fibroma of the uterus.

The patient was put on same prescription as case first and ordered to report in one week. Treatment was carried out as directed, and on July 20, she was able to come to clinic on cable car and reported that she was out of bed and the previous day had done a day's washing. The patient kept on the same treatment, improving in general health with a steady and continuous discrease in the size of the tumors, until October 8th, when she ceased to return to report, no doubt on account of her belief of the uselessness of further treatment, deeming herself well.

At present patient is in bed and, as report says, unable to leave it on account of a stroke of paralysis which occurred in March of present year, 1892. I have no doubt that the present condition of the patient is due to her ceasing to continue the treatment and the consequent growth of the myo-fibroma.

Case III. Mrs. Mary F——, colored; married; no children; came under observation July 13, 1891. Two miscarriages at third month. Menses regular but painful; at times being so severe as to confine the patient to her bed. General health poor. Patient's occupation has been that of a barber for the past thirteen years. First noticed a swelling in the abdomen six years ago. At this time pains were griping in character, coming on daily about 3 o'clock; this condition lasting two months at a time. During this time menstruation was very profuse, of six or seven days duration. Had leucorrhœa and a profuse discharge, watery in character.

Examination.—Uterus pushed forward to pubis; hard tumor irregular in outline lying behind and to right; dense and firm to the feel, freely movable with uterus, springing apparently from the posterior wall of the fundus and extending to the umbilicus.

Diagnosis—Myo-fibroma. Treatment same as first case. The treatment has been continued to Dec. 19, 1892, when the patient was examined and found to have a tumor in the abdomen about the size of the closed fist springing from the posterior wall of the uterus; movable, giving no pain or causing any disturbance by its presence. She is still on the same treatment and able to perform her daily duty at the barber's chair without any pain or inconvenience.

Case IV. Mrs. Tenny M——, colored; age 44; married; has had three children, but no miscarriages; came under observation November 16, 1891. General health good, has been doing washing and ironing for the past eight years. Four years ago, while hanging paper in a room, she experienced a strange feeling accompanied with pain in the right side. This has continued at irregular periods up to time seen. Since this occurred menses have become painful and profuse. Leucorrhœa and profuse watery discharge.

Diagnosis—Myo-fibroma.—Examination showed the uterus retroflexed with a fibroid on right side, twisting and distorting the uterus on its axis. Treatment same as first.

Result: While in this case there has not been a marked diminution in the size of the growth, yet there has been no increase, and the patient has been able to

attend to the duties of life without discomfort. She is at present still on the same treatment and under weekly observations and examination. Menstruation regular, lasting four and five days. Since coming under treatment she has periods of despondency, a fact which was noticed in several others of the cases under observation. Dr. D. W. Prentiss, of Washington, first called attention to this peculiar effect of ergot on certain cases in an article written for the *Amer. Journal of Obstetrics*, December, 1889.

Case V. Mrs. Johanna C——, colored; age 38; married; never pregnant; first seen February 1, 1892. Menses regular, scanty; little pain. General health good up to a year ago. Has done washing for the past thirteen years. About two years ago abdomen began to swell and the urine was retained, making the use of the catheter necessary. Pain has been present from the beginning of the trouble; no leucorrhœa.

Examination shows a hard, round, smooth, dense and firm body occupying posterior cul-de-sac. Cervix pushed high up under pubis with uterus anterior.

Diagnosis— Myo-fibroma.— Treatment same as first. Since treatment menses have been regular, lasting three to four days. Says she does not suffer as much pain as before; no trouble with the urine. The growth has diminished sensibly and the general and local conditions of the patient are such as to warrant a continuance of the treatment.

Case VI. Mrs. Mary A. J——, colored; age 39; married; never pregnant, came under observation June 27, 1892. Menses regular with some pain, profuse and last eight to twelve days. General health fairly good. For the past nine years has kept a store which required her to be on her feet a great deal of the time. About three years ago sold her store on account of ill health, since which time she has been doing her own housework alone. About six years ago excessive menstrual flow began, but patient did not know the nature of her trouble until examined at the clinic.

Has had leucorrhœa and profuse watery discharges; complains of pain and dragging sensation in abdomen, also frequent and painful micturition.

Examination.—The tumor was found to spring from right side of fundus of the uterus extending as high as umbilicus.

Diagnosis — Myo-fibroma.— Treatment same.

Since treatment there was a marked decrease in size of tumor until it was one-half the original size, since which there has been no change. Menses regular, not great in quantity. Patient, on December 19, expresses herself as feeling as well as she has ever been in the past. Complains of periods of despondency.

I will here quote from a letter written to me by my friend, Dr. M. Coryell, of Fort Scott, Kansas. The report will speak for itself:

"On June 5th, 1892, was called to see Miss Z. C——, whom I found suffering from a uterine fibroid. Thinking this to be a good case to try your treatment of salix niger and ergot, I immediately put her on half drachm doses of each to be taken three times daily. This treatment was kept up until the fifteenth day of November when I found her so much better that I stopped their use for a time. She measured around the abdomen, on level of umbilicus, 56 inches; when treatment was begun on June 5th, also the depth of the uterus as measured with the sound was $6\frac{3}{4}$ inches.

When seen and examined on November 15th, she measured around the abdomen, at the level of the umbilicus, $42\frac{1}{2}$ inches, while the depth of the uterine canal had decreased to three inches. She has not had one period of flooding since she began the treatment; while, according to her previous history, she has had from two to three periods of flooding per month for five or six months previous to being put on the ergot and salix niger. I may say, from observation of this case, that the combination of drugs, as recommended by you, will do all that is claimed for them in certain cases."

These cases as reported are the histories of patients with their treatment upon which I have based my observations of the therapeutic treatment of uterine fibroids. They are not manufactured or colored to suit a belief or a theory. They are real, taken from a tri-weekly clinical record and founded upon observation (and I may say an almost daily observation) extending through a period of many months. The only error may lie in the fact that they do not cover a sufficient number of cases and do not extend over a

long enough period of time. However this may be I am of this opinion and shall endeavor to present it to you in the following propositions, which you may take as the result of my observations:

1. That whenever a woman has a myo-fibroma of the uterus she can be benefited either by operation or treatment.

2. That whenever a woman has a myo-fibro-cystic tumor of the uterus there is only one method of cure and that must be operative.

3. That the elective method of palliation or cure in any given case of myo-fibroma must be governed by the condition of the patient and the condition and relations of the tumor present.

4. That the elective methods of treatment of myo-fibromata are palliative, medicinally curative, electricity, operative.

5. That certain cases of myo-fibromata can be and are benefited and rendered entirely inert by the use of properly selected therapeutic agents.

6. That the class of myo-fibromata which are benefited by the use of therapeutic agents are those in which the muscular tissue largely predominate.

7. That the class of myo-fibromata, in which the muscular tissue largely predominates, are reduced in size and rendered harmless by the use of salix niger and ergot. That this does not, however, cover every tumor of this class.

8. Finally, in certain cases, the use of therapeutic agents, if not curative, makes an operative interference safe and of more easy performance; locally by lessening engorgements and loosening adhesions by its contractile effects, and constitutionally by relieving symptoms and thus allowing the attainment of a better general condition.

THE USE AND ABUSE OF TRUSSES.*

AP MORGAN VANCE, M. D.

As far back as history takes us the treatment of rupture has been a problem with which the surgical mind has wrestled; and even up to the present day, the treatment of this ailment, from which such a large proportion of the human family suffer, one person in every eight being the subject of one or the other varieties of hernia, it neither respecting age, sex, nor condition; has any definite procedure been devised which can be relied upon for relief?

Through all ages have all operations and appliances been practiced and used, the number being limitless, yet it is left for some future surgeon, as stated above, to immortalize himself by originating some treatment, yet unknown, before we can claim to cure this trouble.

In the experience of the writer the most perfect results have been brought about by the use of the truss. It is an unfortunate fact, probably due to the meagre results obtained, that the treatment of the hernia by the truss has so largely been relegated to charlatans and unscientific men. This is undoubtedly the fault of the regular profession, few of whom have studied this branch of mechanical surgery, and the common way of disposing of this class of cases by the general practitioner is to refer them to some druggist friend, or, if possible, to some instrument-maker, to have the instrument applied, who, as a rule, exposes his stock of trusses and allows the patient to choose for himself, just as if he was selling a pair of shoes or other article of wearing apparel; the result, of course, being a mere lottery, as it is no uncommon thing to find patients thus treated wearing right trusses on left hernias, or vice versa, or wearing them upside down or otherwise improperly. It is also a daily observation to surgeons who see a number of these cases to find trusses applied, often by the advice of a physician, upon cases of retained testicle, variocele, hydrocele, buboes, orchitis, dropsy of the scrotum, psoas abscesses and what not? This is due of course to the almost universal lack of knowledge, and therefore of interest, in this class of troubles.

The result of this mal-treatment is untold suffering and oft-times death, the vast

*Read before Jefferson County (Ky.) Medical Society.

majority of strangulated hernias being due to the mal-application of a truss.

Of the thousands of trusses of different varieties which are sold there are only one or two which are made upon scientific principles.

Any truss which gains its retentive power by constriction of the body, more particularly all forms of elastic truss, are made improperly, as every movement influences the relationship of the body and pad. Nearly all of the older patterns are made with the idea of producing irritation with the hope that the hernial opening may be closed by plastic deposit; of course, the opposite result is inevitable, as atrophic changes are sure to follow this severe pressure.

The true idea should be to simply prevent the entrance of protrusion into the canal, trusting to the natural tendency towards closure which takes place after the descent of the testicle. Th is tendency is in exact proportion to the youth of the patient, and the length of time the hernia has existed.

Therefore, the truss pad should be more or less flat, and its relationship to the part constant and undisturbed by any movement of the body.

Therefore, those trusses which acquire their force by antero-posterior pressure from sacrum to abdominal ring, without constricting the body, are best. This pattern is known as Hood's Truss. There is no need of any spring pressure, as with this arrangement of the encircling band the pressure can be graduated exactly.

After the proper truss is applied the patient should be carefully instructed how to use it and what is to be expected of his truss. The benefit to be derived, of course, being just in proportion to the intelligence with which it is used. This is oft times very difficult as nearly all patients, before they get advice from a scientific source, have been wearing trusses of various styles and patterns, and invariably think they know more about it than any one else; and almost universally insist upon applying the truss pad over the pubic bone instead of supporting the canal above.

What is known as the French and German trusses are constructed with this end in view and can be applied in no other way.

In the treatment of infantile hernia the problem is much easier, and except in very young subjects the same form truss as described above should be used. In younger children, say up to two years of age, where constant soiling prevents the use of the regular form of truss, the ordinary "T" bandage applied over a pad made of adhesive plaster, is the best form of support. Here the constriction of the body to obtain the requisite pressure is not harmful, as the muscular system is undeveloped, and the soft medium of infantile fat prevents a movement of the pad objected to above. These bandages can be made best of canton flannel and in sufficient numbers that a fresh one can be applied as often as constant soiling requires.

In those young cases where the condition is aggravated the Heatonian operation is very beneficial, simply as an aid to the truss, the temporary deposit of lymph preventing the easy descent of the hernia, and making the constant retention much less difficult.

There is no question but that a certain percentage of radical cures occur after any of the recognized operations, yet no man can conscientiously declare that a cure will result in any case; therefore, should we not apply a light support as a routine practice, or have we the right for the sake of ascertaining the value of one or the other procedures, to allow these cases to go without a support?

Even if an operation should be devised which would positively bring about a radical cure in this condition the abhorence of the knife on the part of the people will prevent the vast majority from taking advantage of it.

Therefore the truss will continue for all time, and it behooves us to educate ourselves in its application and a better understanding of its use, that these sufferers may be more scientifically treated.

Dr. J. B. James (*British Medical Journal*) states that he has been treating hæmorrhoids for years by simply applying calomel locally, and without exception his treatment has been successful, especially when inflammation was obvious in the hæmorrhoidal mass, characterized by mucous discharge and hemorrhage. Under this simple treatment the symptoms are speedily relieved, with the still more important subsequent advantage of the patient's restoration to health.

SOCIETY REPORTS.

JEFFERSON COUNTY, (KY.,) MEDICAL SOCIETY.

Meeting of March 15th, 1893.

"The Use and Abuse of Trusses," by Ap. Morgan Vance, M. D. (See page 687).

DISCUSSION.

DR. W. L. RODMAN: I think Dr. Vance has called attention to a very important subject; he could scarcely have selected one of greater importance than the use and abuse of trusses. It certainly is a subject that every practitioner in medicine and surgery should take a great deal of interest in, on account of the frequency that these cases are met with in practice. I have sometimes thought, however, that herniæ are not as common as the text-books tell us—some say one person in every thirteen, others one in every ten; Dr. Vance states, I believe, one in every eight. Certain it is that these conditions are very common, but it leads me to say that my own individual experience has not furnished the great number of herniæ one would expect from reading books. I examine on an average from 200 to 300 men for life insurance each year, and I am quite sure that in those subjects I examine I do not strike more than one case in twenty-five or thirty who has a hernia. I do not examine, however, many laboring men, and this may explain the small number of herniæ I meet with in life insurance risks. One man's experience is entirely to small to base statistics upon, or to form an opinion from. Certainly, from my experience, I cannot think that herniæ are as common as we are led to believe.

I fully agree with everything Dr. Vance has said on this subject; he is certainly correct in urging that every man who treats hernia should be very careful to write a note sending the cases to an instrument-maker rather than to refer them to a drug store; this is something that I never did in my life and never shall do. I see that the measurements are correctly taken and instruct every case of rupture to go to an instrument-maker and have a suitable truss adjusted and then report to me again. If the instrument-maker knows this is to be done he will be more careful in adjusting the truss, than he otherwise would. I think, as Dr. Vance has said, there is so much uncertainty (and some little danger) attending the operations for radical cure of hernia that probably the best thing to do is to follow the old practice of fitting each case with a truss and asking him to wear it the rest of his life, or so long as it retains his hernia and does so comfortably. I have rather undergone a change of heart in regard to the radical cure operations in the last year or two. I have done the operation a few times and have been successful in every instance. I have insisted upon the patients wearing a spica bandage, or some kind of light truss, for several months after the operation. I have changed more from what I have read than what I have done, because my cases have been so few as to hardly warrant me in making the change. When one reads of the number of operations done by MaCewan, Kocher, Bassini, besides Bull, McBurney, Marcy, and other men in this country, we are struck with the fact that they do cure a great many cases; in fact, the vast majority have gotten well after radical operation. I do not consider that any operation is a *radical cure* where you must supplement it by the continued use of a truss. The dangers of the operation in experienced hands are not great, still there is some danger in it. I do not believe a man will meet with more than two or three deaths in 100, possibly statistics do not indicate as large a death rate as that. W. T. Bull, of New York, has probably done more operations for the radical cure of hernia than any one else in this country. I remember he read a paper before the American Surgical Association three years ago. He reported 134 cases that he had operated upon, losing but two cases, I think. He operated upon very young children and very old men and women—some over eighty—taking the cases just as they came, in his operations at the Hospital for the Ruptured and Crippled, as well as other hospitals in

New York. Bassini, Kocher and MaCewan claim even better results than this. Bull is not very enthusiastic over the operation. He thinks that in a majority of cases the hernia recurs. He remarked to me the last time I saw him in New York, that "it was a nut for somebody else to crack; that no one had ever proposed a certain operation for the cure of hernia." I believe, however, that we strike cases very often where we are perfectly justified in advising the patient to have a radical cure performed. I think I have such a case now, a young man, twenty-four or twenty-five years of age, who has had inguinal hernia for a number of years, and has been three times to see me, urging the propriety of operation for radical cure.

The reason he has been talking about radical cure, is, I find, that he is very intimate with a medical student, rather a recent graduate, who has spoken about the propriety of having his hernia operated upon. I have declined each time and told him that as long as the hernia could be held up comfortably and safely I thought he should persist in the use of the truss, that while it would not cure him—because he had already worn it for seven years—still I thought it was better to wear it the rest of his life than to submit to an operation. He has rather "kicked over the traces," lately, and it was due to the fact that he was out taking violent exercise two or three weeks ago and the hernia came down, the truss probably getting out of fix some way, and he was laid up for a few days. He now says he is not going to wear a truss any more. In a case of this kind I think it is our duty to operate. I think he will be altogether in a safer condition by having a radical cure performed, rather than go without a truss, as he now does—he positively refuses to wear one any longer. I do not consider that the danger is very great; however, if I should operate upon him I should insist upon his wearing a light form of truss for three or four months afterward. I have seen some excellent results from radical cure operations for herniæ. I have spoken differently in societies before this, but I have watched cases in the practice of other surgeons, have also had a few myself, and have been reading a great deal upon this subject in the last year, and am fully persuaded now that a great many of these cases should be operated upon. In people who absolutely refuse to wear a truss, and who cannot be made to appreciate the fact that they take their lives in their hands every time they go out for a walk without one, an operation should be advised.

Dr. J. M. Krim: What would you consider as the greatest age at which a truss may be applied with the prospect of a permanent cure?

Dr. A. M. Vance: I have seen several cases in men over thirty that were cured by the truss. I think it depends entirely upon the intelligence of the patient and what is to be expected of him. He should never rise without the truss on, and there are a great many little things that should be taught a patient who is to wear a truss—no truss will sustain a sneeze, and every man who wears one should put his hand in his pocket and support the truss while sneezing. If a truss is applied early, we are apt to get a rapid result. I think perhaps the cure of herniæ in early life is simply the tendency that these parts have to contract, like the contraction after the descent of the testicle.

Dr. Trunnell: What is your experience with peritonitis following a ventral hernia, for instance, caused by violence? In the case I refer to there was marked strangulation, and after reduction there were distinct evidences of peritonitis for some time. There was complete cure of the hernia, and I believe the peritonitis following reduction had something to do with preventing return of the trouble.

Dr. A. M. Vance: I have never seen any marked peritonitis in cases of hernia. I remember seeing one case of incarcerated hernia in a woman; upon reduction she had a great deal of pain and some fever, which however passed off after giving salts. Possibly peritonitis assisted cure in the case referred to by Dr. Trunnell by thickening the peritoneum.

I agree with Dr. Rodman in what he says concerning the radical operation for cure of hernia, except that I think it is a misnomer until we can get something absolutely sure. I operate, of course, upon cases where I cannot do good work with the truss. I would not hesitate for a moment to operate upon the case he speaks of. I think the surgeon should fit the truss himself as he is the one to teach the patient its use.

PHILADELPHIA ACADEMY OF SURGERY.

Meeting March 6, 1893.

THE PRESIDENT, Dr. William Hunt, in the chair.

John B. Deaver presented a paper on

AMPUTATION AT HIP JOINT: ENCYSTED CARTILAGINOUS TUMOR NEAR SUBCLAVIAN VESSELS: OPERATION ON THE FIFTH NERVE.

Mr. President and Fellows of the Academy: I will first present a case of amputation at the hip joint, done for osteomyelitis of the femur. At the time of the operation the patient was very much depressed from sepsis, consequent upon prolonged suppuration. The only point of interest in the case from an operative point of view is that during the amputation hemorrhage was controlled simply by an Esmarch tube applied round the thigh, above the trochanter and along the crease of the groin, being retained here by two pieces of bandage, one passed beneath the tube in front and the other beneath the tube behind, each of which was held by an assistant. An oval flap of skin and fascia was made, and the muscles divided down to the bone by a circular sweep of the knife. The superficial and deep femoral arteries, with their accompanying veins, were next tied separately, as well as those of the muscular branches which could be recognized. The tube was next loosened a little, and the small vessels, as they bled, caught with hæmostats. The tube was now removed, and an incision carried from the external angle of the wound up over the trochanter and into the joint dividing the capsular ligament, when the muscles were carefully separated from the bone and disarticulation completed. The amount of blood lost, I do not think, amounted to more than two ounces. The advantage this procedure offers over the Wyeth method is in not dividing the femur before the disarticulation is made, and further, that the amount of blood lost is not any greater, and that the vessels not being constricted for so long a time, there is less likelihood of consecutive bleeding.

The tumor I here present is one of sarcoma, removed from the side of the neck, which had its origin from the periosteum of the vertebræ. The symptoms presented by the patient were those of laryngeal obstruction, paroxysmal in character and attended by the expectoration of large quantities of mucus. The symptoms of obstruction were not caused by pressure inflicted upon the larynx or traechea, but from involvement of the laryngeal nerves. Before the operation was performed I very much questioned if the removal of the growth would suffice to relieve the obstruction, which was afterward proven by the same symptoms continuing until death, twenty-four hours thereafter. The dissection was not a very difficult one, as the mass lay behind the large vessels, the pulsation of which was scarcely perceptible. The great amount of infiltration around the vessels must by necessity have involved the laryngeal nerves as well.

The second specimen is one of cyst, in the wall of which is a circular piece of cartilage. It was removed from the subclavian region of a man who was injured at the battle of Appomattox, April 9, 1865. When the accident occurred he was standing under a tree. He was not able to say, definitely, whether the injury resulted from being struck by a piece of shell or by a piece of wood from the tree. The only noticeable trouble at the time of the accident was fracture of the clavicle. From that time to the present a sinus has existed in the neck which patient states has been operated on without success. He was referred to me by Dr. Hildenbrand, when, upon examination, the orifice of the sinus was plainly to be seen, immediately above the inner end of the left clavicle, from which was escaping a purulent discharge and through which, upon the introduction of a probe, could be felt, what was believed, most probably, to be dead bone. Examination with the fingers demonstrated the presence of a partly movable mass which was thought to be a detatched piece of the clavicle which had undergone necrosis. Operation revealed the presence of this cyst; it was attached to the sheath of the

subclavian vessels and to the pleura. Examination of the clavicle through the wound showed no trouble other than a slight enlargement at the seat of the original fracture. Examination of the cyst wall demonstrated very clearly the presence of cartilage.

T. M., aged fifty-eight years, white, Irish, slate-roofer; from a child had been very nervous, the slightest excitement or undue exertion throwing him into paroxysms of nervousness. When twenty-eight years of age, had an attack of small-pox which was followed by a weeping sore over the right inferior maxilla. This continued to discharge for six years, when it healed. Immediately after the healing of the sore he was attacked with neuralgic pains which were referred along the course of the inferior dental nerve. This pain continued at irregular intervals for six years, when he consulted a surgeon, who was supposed to have removed a section of the nerve near the dental foramen. Very little, if any relief followed this operation, when a second was performed by the same surgeon one year later; this was followed by relief for one year, when he had another attack of the pain. He now came under my care. I trephined the inferior maxilla over the angle and removed a section of the inferior dental nerve. This was followed by relief for a period of fifteen months, when the pain again returned. I now opened up the field of the old operation, exposed the proximal end (stump) of the nerve, excised a part therefrom, chiseled away the roof of the remaining portion of the dental canal, and removed the distal portion of the nerve as far as the mental foramen. This was followed by relief for sixteen months, when the pain returned, being referred, in addition to along the course of the inferior dental, along the side of the tongue. I now simply cleared out the field of the old operation, but this was not followed by any marked relief. I again operated, this time taking out a vertical section of the ramus of the jaw as far as the sigmoid cavity, and removed a further section from the proximal end of the inferior dental, and at the same time a section from the gustatory nerve. This was followed by relief. I purposely refrained from taking a section from the inferior maxillary nerve immediately after it passes through the foramen ovale, also from performing an intra cranial operation, as I am not as yet, by any means, convinced that these more radical procedures are warrantable until the milder ones have been done without success. I can recall a number of cases, both of neuralgia of the inferior as well as of the superior maxillary nerve, where I have followed this course in relapsing attacks, with satisfactory results, to convince me that a longer period of relief from pain is offered the patient than would result, perhaps, by the more radical operations, removal of the Gasserian ganglion, etc., in the light of the present statistics.

DISCUSSION.

Dr. John B. Roberts: Twice I have had occasion to remove large malignant growths from the neck, and in both cases the result was the same as in Dr. Deaver's case. In one case, a child, I had to tie the internal carotid artery, and the child died on the second day with symptoms of brain implication. The other case was that of a man with a deep tumor requiring ligation either of the internal jugular vein or of a large branch close up to the vein, I now forget which. I thought that he was going to get well, but he died on the fourth or fifth day with symptoms, the origin of which I could not determine. The wound was aseptic and nearly healed. He was found to be breathing very rapidly, and sank in a few hours in a sort of collapse. I could not tell whether there was implication of deeper organs or heart clot. No autopsy could be obtained.

Dr. J. Ewing Mears: In the case which I reported and to which reference has been made by Dr. Deaver, I removed two and one-half inches of nerve and submitted it to Dr. DeSchweinitz for examination, and the condition found was that of fatty degeneration. It is important, it seems to me, that our studies should be directed toward ascertaining if possible, what the pathological condition is in these cases of trifacial neuralgia. I think that all of us have come to the conclusion that operative procedures appear, in most cases, to be hopeless so far as permanent relief is concerned. It is possible that from studies in regard to the cause of the condition, we may be able to indicate some method of operation which may prove more successful.

Last spring the members of the American Surgical Association were shown in the Massachusetts General Hospital the results in five or six cases of operations upon the second and third divisions of the fifth nerve for neuralgia. In these cases an incision had been made over the temporal region, the muscle cut through and the zygoma divided. By pressing the tissues down firmly the operator was able to reach the second and third divisions as they emerge from the foramen rotundum and ovale. In these cases the relief had extended, if I remember correctly, over three or four years, and in one case five or six years. From the reports which are given in Boston, this appears to be a very successful operation.

To my mind, the question of interest is in regard to the pathological condition. If the disease is of central origin I do not see how any operation on the peripheral terminations of the nerves can be of service. Repeated operations, such as Dr. Deaver performed, of course, give temporary relief.

Dr. W. W. Keen: I quite agree with Dr. Mears that the question of the pathology is a most important one. In the cases where I have had a microscopical examination made the change has been found to be one of sclerosis. In one case there were spots of distinct hemorrhage into the nerve. These were almost macroscopic. I have never seen the inferior dental nerve so large as in this case. That patient had a return of the pain, and a second operation was done. So far as I could determine, a new nerve had formed, and, strange to say, there was a branch of this nerve which went inward through a foramen on the inner surface of the jaw. I saw no such foramen at the first operation. Dr. Dana some time ago published a paper in which he stated that he had found sclerosis of the vessels rather than of the nerve. However this may be, it seems to me clear that the sclerosis of the vessels or of the nerve is the chief thing, and that this is a distinctly senile change. That it does not appear in early life we all know, but only in later life, when sclerosis of other organs appear. This being the case, I think that the operation of choice should always be the peripherial operation. I should not think of endeavoring to remove or break up the Gasserian ganglion as a primary operation. I was told the other day that one of Mr. Rose's cases had shown symptoms of return, and this is what might be expected, as the sclerosis begins rather in the periphery and works backward. While medicine offers no benefit in the majority of cases, we can, as a rule, assure a patient that an operation will afford at least one or two years of relief. I presume that some of Dr. Deaver's operations consisted simply in reaming out the connective tissue about the stump of the nerve. This I have done in more than one case and, although under the microscope no nervous tissue could be found in the material removed, the operation gave as much relief as followed a pure exsection of the nerve. This being the case, it seems to me that we should, as a general rule, endeavor to give relief by such a simple operation rather than immediately to go to the foramen rotundum or ovale or within the skull and remove the Gasserian ganglion.

I noticed that Dr. Deaver referred to destruction of the ganglion as not a serious operation. I should consider it quite a serious operation, although there have not been a large number of deaths. Rose has done it six or seven times, with one or two deaths. Andrews four times, without a death. Hartley once, with recovery, and Dr. Roberts once, with recovery. Besides this, two eyes, and possibly more, have been destroyed. It seems to me that any operation involving so much traumatism is to be considered a very serious operation, and should not be undertaken except after the gravest consideration.

Dr. James M. Barton: As has been said by Dr. Mears, we have not yet arrived at the pathology of neuralgia. One suggestion is, that it is due to small aneurisms, which have been found in the diseased nerves. This view is supported by the results of the ligation of the external carotid for this affection. Nussbaum claimed that one-half of the cases are permanently cured.

I can also confirm what has been said by Dr. Keen. The most trifling operation on the nerve, the slightest stretching, even the division of the distal branches is apt to afford temporary relief, and the most serious operation will not do much more.

So rare, in my experience, is anything like permanent relief, that I exhibited before this Society, a few months ago, as

something unusual, a case of neuralgia of the second branch, of thirteen years' duration, in which I removed the nerve at the foramen rotundum, and where the relief had continued for five years. The man is still free from the disease.

Dr. Thomas G. Morton: I am at present attending a patient, who is now eighty-two years of age, on whom I operated some twenty years ago. After the excision he had entire relief for many years; then had a recurrence of pain, brought on, apparently, by a ride of five miles in a wagon which had no springs, in which he was severely jolted.

For the last ten or fifteen years, although enjoying, indeed, robust health, he has, at times, suffered intensely, and then again having entire immunity from pain. Now the suffering is only relieved by morphine injections. Swallowing, talking, any movement of the tongue, touching the skin of the face, or even the beard, provokes "thrusts of pain."

In another case—now more than twenty years since the operation—the patient has had entire freedom from pain. As a rule, sooner or later pain reappears; but in such cases there is no reason why the operation should not be repeated. Benefit is generally experienced from each operation, and for even a measure of relief, patients are willing to submit to any treatment.

William J. Taylor, M. D.,* presented a report of

A CASE OF FRACTURE OF THE THYROID CARTILAGE.

Charles E., forty-three years, a carpenter, was admitted to the surgical ward of St. Agnes' Hospital on October 6th, 1892, in a semi-unconscious condition. He was unable to give an account of the accident. but a fellow workman reported that he had fallen a distance of about twenty feet, from a scaffold upon which he had been working. No one saw him fall but when he was discovered he was unconscious and lying across a heavy piece of wood. When admitted into the hospital, a short time afterward, he was unconscious, could be roused from his stupor, but could give no account of himself. He was very much shocked. The right side of his face was badly contused, the right eye swollen and completely closed. He was bleeding from the nose, mouth, and left ear, and his general appearance was that of a man suffering from a fracture of the skull. The pupils were equal, and a very careful examination showed this diagnosis to be an error. He had great difficulty in breathing, could not swallow, the saliva ran out of the corners of his mouth, and when he attempted to speak his voice was husky and his articulation very indistinct; he could not speak above a whisper, and only that with the greatest pain and difficulty. There was little or no swelling of the neck, but when he regained complete consciousness he complained of great pain and discomfort in the throat.

A careful examination revealed a fracture of the thyroid cartilage on the right side, extending from above downward about on a line with the insertion of the thyro-hyoid muscle and about two lines anterior to it. The amount of displacement was very slight, but the mobility of the fragments could be easily demonstrated, and the fragments displaced and replaced again by manipulation with the fingers.

Dr. Smock, the laryngologist to the hospital, very kindly examined him very shortly after his admission, and confirmed the diagnosis of fracture of the thyroid cartilage. He reported also a rupture of the tympanic membrane about at the extremity of the manubrium process of the malleus. The nose showed hemorrhagic points on the septum on both sides.

Dyspnœa was pronounced, but there was apparently no emphysema about the seat of the fracture or in the neck. His symptoms were severe, and the pain and discomfort very great, but I did not think them sufficiently so to demand immediate relief.

Dr. White, the resident surgeon, was instructed to make all preparations for instant tracheotomy, and to send for me if the symptoms should increase in severity. He was to use his own judgment, however, and to operate at once without waiting for me to arrive should the necessity arise. No attempt whatever was made to apply a dressing. For some days the bleeding from the mouth persisted, and the difficulty in swallowing

*Surgeon to St. Agnes' Hospital; Assistant Surgeon to the Orthopædic Hospital and Infirmary for Nervous Diseases, Philadelphia.

and dyspnœa continued, but gradually lessened, and by the end of three weeks was entirely gone. His voice still remained somewhat husky, but there was no longer pain or difficulty in swallowing. The left ear was treated by cleaning out the auditory canal with cotton, and insufflating daily aristol and boric acid.

Dr. Taylor read another paper on

MULTIPLE FRACTURE OF BOTH UPPER EXTREMITIES.

Margaret C., aged fifty-six years, a widow, and by occupation a monthly nurse, was admitted to my ward at St. Agnes' Hospital on the evening of October 19, 1892, suffering from the most remarkable number of fractures, considering the amount of constitutional disturbance, it has ever been my fortune to see. She was going down the cellar stairway in the dark when she missed her footing and fell to the bottom, some eight or ten steps. From the nature of the injury she must have put out her hands before her in the hope of breaking the fall.

She was unconscious for a short time, and was then brought to the hospital in a patrol wagon, but recovered sufficiently to walk from the wagon into the receiving ward.

Upon examination it was found that she had received a lacerated wound of the scalp, six inches long and extending down to the bone, and a deep lacerated wound of the lower lip about two inches in length. There was a fracture of the surgical neck of the left humerus and an oblique fracture of the middle one-third of its shaft; a contusion of the left elbow and a fracture of the lower end of both the radius and ulna of the same side. There was a supra-condyloid fracture of the right humerus extending into the elbow-joint, forming a T. A fracture of the upper third of the radius and of the ulna, and a fracture of the lower radius. In spite of this great number of fractures and of the serious lacerated wounds she was able to walk into the hospital, and seemed to suffer comparatively little pain. Her temperature was normal, her pulse good, and there was no evidence of shock such as would have been expected from the nature of her injuries.

There was much difficulty experienced in adjusting and holding in place the different fractures, but with care and patience and plenty of plaster-of-Paris this was accomplished. Her recovery has been most satisfactory, and she has for all practical purposes full use of both arms.

Such an extensive number of fractures led me to suppose there must have been some serious lesion of the bones, but the most careful inquiries failed to give me any clue to such a state of affairs. She was a large, strong, and, apparently, perfectly healthy woman. She had never before had a fracture of a single bone, neither was there any history of fracture in any member of her family. She was born in Ireland, and had lived there until a few years ago, and had always been in good health and a hard worker.

DISCUSSION.

Dr. H. R. Wharton: Some years ago the President investigated the subject of fracture of the larynx and proved that tracheotomy was indicated, and that patients usually did better after this operation.

I would ask the experience of members in regard to multiple fractures, whether they have found much constutional disturbance or many cases of sudden death following multiple fracture. My own experience has been that generally patients do well. Last summer I had under treatment a boy six years old, who had fallen off of one of the tunnels of the B. & O. R. R., and sustained a compound fracture of the nose, fracture of both bones of each forearm, and fracture of both thighs about the middle of the shaft. The patient did perfectly well with normal temperature for a week. He was doing well when I last saw him at 12 o'clock. In the evening of the same day the resident noticed that his breathing was peculiar, and an hour afterward the patient was moribund. He died of some cerebral complication. I thought that it might be a case of fat embolism which is said to follow fractures. I have seen another patient die very much in the same way with a simple fracture of the femur. No post-mortem was made in either case.

The President: The conclusion of the paper which I wrote on fracture of the thyroid cartilage was that where emphysema and bloody sputa were present there had been up to that time no recovery where tracheotomy had not been

performed. I thought that tracheotomy should be done when the first symptoms were discovered. I found several cases similar to that reported by Dr. Taylor in which recovery followed without tracheotomy.

Dr. Thomas G. Morton: Some years ago I saw in consultation a lady, eighty-four years of age, who had gradually during ten years lost her vision from cataracts. Soon after this she sustained in a fall a fracture of both bones of the forearm, the humerus about the middle and the shaft of the femur near the great trochanter. Complete recovery from these injuries following showed such an excellent repair, that six months afterward I operated upon both eyes at the same sitting. Perfect vision followed in each, which continued until her death when in her ninety-seventh year.

Thomas S. K. Morton, M. D., then read a paper on (see next week.)

METATARSALGIA—WITH AN ACCOUNT OF SIX CASES CURED BY OPERATION.

DISCUSSION.

Dr. W. W. Keen: This affection has not seemed to me to be so frequent. I have seen only one case—this was a lady about going to Brazil. I operated five years ago on both feet. Since then she has been able to walk perfectly well and to dance.

Four years ago I had an attack which I thought might be the same. This attack interested me in connection with the diagnosis, because I had every symptom that Dr Morton has described. The attack came on about the time of my summer holiday, and I was unable to walk without limping from the excessive pain. When the pain came on I was compelled to go to my room or sit down where I happened to be, and remove the shoe. I had a pair of shoes made with a thicker and wider sole and a little larger, but without relief. When I came home I was tempted to have the operation done. I, however, consulted my friend, Dr. J. C. Wilson, who suggested a gouty origin, and put me on appropriate treatment, and the pain disappeared, and I have been perfectly well ever since. I mention this in connection with the diagnosis, as here there was the pathognomonic sign of having to sit down and remove the shoe when the pain came on.

Dr. Thomas G. Morton: As early as 1870 my attention was first directed to this painful affection of the foot, and I then felt satisfied that I had a malady which had not previously been described. In the *American Journal of the Medical Sciences* for January, 1876, I published an account of this painful local affection, and subsequently reported a number of cases which I had successfully operated upon. Later, in various journals the subject received attention until at present the disease is generally understood. In 1891, Dr. E. H. Bradford published an interesting account of a number of cases which had come under his care, and more recently numerous authors have given their experience.

A medical man from Hagerstown, Md., once called upon me and stated that he was seeking relief from a neuralgia of the foot, which was so terrible that he was willing even to submit to amputation of the limb. The only relief he obtained was by injections of morphia. The operation was completely successful, and the doctor went to his home on the third day afterward, and has never had any pain since.

I have generally found the disease in one foot; but occasionally in both, and have operated on both feet at the same sitting. Now and then I have amputated the toe instead of resecting the joint. The pain in many cases is slight, and only requires a proper shoe and a flannel bandage to keep the toes from rolling; in others nothing except an operation will suffice. In regard to shoes, a shoemaker of this city told me that one of his customers had more than fifty pairs, hoping in each new pair to have greater relief.

The point has been raised as to whether the painful nerve might not be excised instead of excising the joint of the toe. I apprehend there would be great difficulty in finding the nerve, and unless all the soft parts surrounding the joint were removed, some branches would remain; while if the pain is due, as I think it is, to the peculiar relation of the fourth joint as compared with the third and fifth, no treatment except joint removal will answer.

W. W. Keen, M. D., presented the following

METHOD OF OPERATING ABOUT THE FACE BY WHICH BUT LITTLE BLOOD ENTERS THE MOUTH.

I wish to call attention to a method of operating about the face which is not generally followed and which may be new to some. It is particularly applicable to epithelioma about the lip, of which I have had two severe cases in a comparatively short time. In one there was extensive epithelioma requiring the removal of a portion of the upper lip, the lower lip, and the cheek. The other case was one of epithelioma of the cheek, and is also of interest from the fact that the patient had originally been operated on forty years ago by Dr. George R. Morehouse. A microscopical examination was made at that time, and the tumor was said not to be epithelioma. When I saw the man the disease extended from the angle of the mouth back to the molar teeth, and from one jaw to the other. It was on the inside of the mouth exclusively, except at the angle where the entire thickness was involved. The external layer of the cheek seemed to be entirely free. In operating I placed the patient on a flat table with the operated side turned a little down and cut through the skin down to the mucous membrane, but not through the latter. I then secured all the vessels *before* opening into the mouth. In this way I prevented blood from entering the mouth and also lessened the total loss of blood. In this case Stenson's duct was involved in the operation. I found the duct and stitched it to the mucous membrane of the upper jaw, and there has not been the slightest trouble from fistula. The incision was a very wide V, the linear incision corresponding to the apex of the V being on the cheek, and the widest part is the base of the V inside the mouth. I am sure that those of you who try this method will find it satisfactory.

William Hunt, M. D., reported

A CASE OF APPENDICITIS.

This specimen was removed from a young girl who presented every sign of good health, but had been sent to the Pennsylvania Hospital by a physician outside, who had diagnosed possible stone in the bladder from the general symptoms. She was examined by the residents on admission, and they thought that they felt a stone. I saw the patient but once and I examined her for stone, but did not find one. I decided to let her rest and repeat the examination under ether the following day. At three o'clock she was taken with severe pain in the lower part of the abdomen. At eight o'clock she seemed to be doing well, but at eleven o'clock there was a return of the symptoms, and she died in two or three hours.

The coroner's physician was sent for and made an examination, and the death was ascribed to "idiopathic peritonitis." I and Dr. Morton were telephoned to this effect and immediately sent back word to make further examination. It was then found that the appendix was large and swollen and had a large perforation in it. The abdomen was full of pus. It was afterward learned that she had been ailing for two weeks, but there were no symptoms referable to the appendix.

DISCUSSION.

Dr. Thomas G. Morton: I have seen more than one case where it was impossible to make a diagnosis; the most remarkable instance was the following: In March, 1890, Dr. DaCosta and I were summoned to Trenton, N. J., to see a patient with Dr. Phillips, of that city. The patient was about forty-two years of age; he had been apparently in excellent health three days before; he became obstinately constipated and had nausea and had vomited; little or no abdominal pain and no swelling, a normal temperature, no chills, and pulse showed no acceleration. The bowel simply refused to respond to cathartics. Inquiry showed that there had been no former attack of pain in the appendix region. Calomel and fractional doses of podophyllin were given.

The following day there was a subnormal temperature and great prostration, but no evidence of local or general peritonitis, and the diagnosis could not be cleared up. Median exploratory abdominal section showed a foul abscess in the right iliac fossa; an inflamed gangrenous appendix; the ileum was covered with lymph, and for several inches showed structural change. Two days subsequently the patient died.

In reviewing this case I can see no way by which the nature of the case could have been determined; it seems hardly possible that perforative appendicitis and intestinal gangrene should not present at least some positive symptoms, yet in this instance, none such were present.

Dr. W. Joseph Hearn: I had a case at the Jefferson Hospital where the man had walked to the hospital the evening before, with a temperature of 101°. Dr. Keen saw him the next day, and we agreed that it was a case of appendicitis. Operation was done and a quart of pus evacuated. The man died subsequently.

Dr. T. S. K. Morton: In this connection, as illustrating how patients with very serious disease are able to perform almost incredible exertions, I may mention a case of strangulated hernia that walked to the Polyclinic Hospital to-day —quite a long distance—after his physician had made strong taxis for half an hour. The strangulation had existed for five days, and when I operated, the gut was found gangrenous.

Artificial Introduction of Labor.*

By H. Fehling, (*Berl. Klin. Wochen.*, 1892).

The author hopes by the improved methods of antisepsis or asepsis to reduce the number of Cæsarean sections by artificial induction of labor. The time for the induction of labor should not be before the thirty-fifth and not after the thirty-seventh week. A contracted pelvis is the most frequent condition which calls for the induction of labor, particularly flat pelvis.

The operation is not so satisfactory in a generally contracted pelvis. A careful examination is in all cases necessary. Particular attention should be given to the fact that in multiparæ there is usually an increase in the weight of each successive fetus. The operation should not be practiced where a pelvis is less than seven cm. in its true conjugate.

In light cases of osteomalacia, normal delivery may be expected since the pelvis may admit of some stretching. Further indications for the induction of artificial labor may be recognized in cases of retrocervical fibroids, and all tumors of the bony pelvis, as also in cases of marked inflammatory masses situated in the pelvis; the cases, however, which call chiefly for this treatment are those of chronic parenchymatous interstitial nephritis.

Cardiac diseases rarely produce symptoms sufficient to consider this operation; on the other hand, however, advanced cases of tuberculosis may serve as an indication.

A careful measurement of the pelvis is in all cases the most important, and the theories of Muller, who states that the induction of labor should not be practiced as long as the child's head can pass into the pelvic cavity, deserve careful attention, as well as that of Prochownick, who places stress upon an anti-fat treatment, which consists in avoiding all carbo-hydrates and fluids.

In order to facilitate the dilatation of the os internum he advises warm, not hot, vaginal douches six to twelve litres, twice daily. If this remains without the desired result an elastic bougie should be passed into the uterus and allowed to remain there several days, in case no fever presents itself.

If the pains have set in, a normal spontaneous delivery may be expected, all operative procedures are contra-indicated unless fever should set in.

*Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

"Mamma, be late suppers bad?"

"Yes, my child, very bad."

"What makes 'em bad?"

"Why, it injures the health to eat just before going to bed."

"Oh, I thought maybe it injured the health to go to bed directly after supper."

The official reports of the cigarette manufacture, which are carefully taken by the Internal Revenue Department, gives a total of 16,581,646,440 cigarettes as the output for the past eight years. Taking the average length of each cigarette at three inches, this would make a total of 4,145,411,611 feet for the entire roll. Dividing this by 63,360, the number of inches in a mile, would make a total of 65,426 miles, or a cigarette girdle extending nearly three times around the earth. Calculated at the lowest retail rate of 50 cents per 100, the cigarette smokers of the United States spend $16,052,019 a year on their hobby.—*Nat. Med. Rev.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 6TH, 1893.

EDITORIAL.

MEDICAL SCHOOLS—THEIR MANAGEMENT.

Elevate the standard and improve the course of study in our medical schools is the cry which burdens almost every presidential address at the medical society meetings of each recurring year. This is commendable. It is a much needed reform. The standard raised, the course of study made broader and more generous, the time lengthened, and those small and puny mushroom schools which have sprung up like Jonah's gourd will, like it, wither within the coming day. Schools which now exist only as an advertisement for men who aspire to the rank of professor, without possessing the qualifications such a title should carry with it, will then disintegrate for lack of students.

The education of the laity must proceed hand in hand with the elevation of the medical standard till they no longer ask whether the doctor possesses a diploma, but whether that diploma is sufficient guarantee that he has pursued such a course of study as to fit him for the responsibilities of his duty as medical guardian of his community. The public must discriminate between the M. D. granted by the school which requires but two years' attendance on didactic lectures for a few months only and that given by the school which, richly endowed with every facility for acquiring knowledge, sends its graduate out fully equipped for his struggle with disease and death. People are too apt to look only at the title and judge one doctor as good as another without pausing to think what training he has had to entitle him to their confidence.

When the mere possession of a diploma does not carry with it a license to kill or cripple and when the practitioner of medicine must give some proof of his qualifications before he is permitted to take the health and the lives of his fellows into his care, then will students seek the best, and our great schools, located in large cities, possessing every laboratory and clinical facility for imparting instruction, will have classes worthy to be taught by the ablest men. The law of the survival of

the fittest will operate to the benefit of both the doctor and the doctored. Such a medical millennium is devoutly to be wished by all who have no axes to grind and who desire only that which conduces to the welfare of suffering humanity.

That such a state of affairs does not now exist, is due to the apathy of the public in regard to such matters, to the selfishness of would-be professors and the conscienceless egotism of small medical politicians who constitute a class of medical parasites which infests every small city, and is not entirely wanting in our larger ones, and who, vermin like, seek their own sustenance at the expense of every thing upon which they fasten.

The reforms just enumerated, while much to be desired are only a little of what must come, ere a medical education can be sought by the young men of our land under as favorable conditions as can be found in the pursuit of the various other lines of knowledge that go to make up a liberal course of study.

Too little attention by far is paid to the health and comfort of the student. In fact medical colleges as a rule set at naught every law of hygiene and violate every principle which conduces to a better understanding of the laws of health. Their students are rushed from clinic to clinic and from didactic lecture to laboratory or dissecting room until they have scarcely time to eat or sleep. The lecture rooms, laboratories and hospital amphitheatres are crowded and poorly ventilated. The foul air which the young disciples of Aesculapius are compelled to breathe has an enervating effect upon both body and mind. Young men often come away at the end of the finishing year feeling as though the battle of life was almost ended instead of having just begun.

Most of the schools are poorly lighted. Very often they depend largely upon a sky light over the centre or have to resort to artificial illumination in order that the work may proceed. They are as poorly warmed as lighted and, while parts of the center are scorched by the heat that brings to mind that place not named in the "*New Edition*," the circumference of the circle is suggestive of "Greenland's icy mountains." Add to all these defects the fact that filth itself is personified in the arrangements and furnishings of the different rooms and we may well marvel that students accomplish anything amid such environments.

The methods of selecting or appointing teachers or members of the faculty cry just as loudly for reform as any other part of medical college machinery. In the first place to get a position as a member of the faculty in some medical colleges requires more "influence" than learning and much more politics than brains. In the majority of cases the learned and successful men of the profession are too busy or too earnest to turn their attention to medical politics; and a scramble for place is so foreign to their mental make-up that they let positions go to mediocrity and brazen effrontery rather than enter a contest with men immeasurably their inferiors. Men who have nevertheless elevated skullduggery to a position as one of the fine arts.

When politics has exhausted itself, chairs have been known to be huckstered out to great wealth or family influence. Some noble sire with a large bank account has a relative whose mental endowment is not built on the same specifications as his dady's or his uncle's certificate of deposit. Things are then evened up by substituting a noble metal for a noble mind.

If the wealth that is given for erecting a new school in order that its founder's name may be known among men—schools that lead a precarious existence for lack of funds to properly carry on their work—if such wealth be applied to the endowment of schools already existing and earnestly endeavoring to give their students the best

training possible, then the men who, by their hard work and ceaseless application, have produced results that well entitle them to the position of teachers will have some inducement, beside the empty rank of professor, to lay aside the druggery of practice and devote their time to the proper education of our medical classes.

There is a practice too of keeping young men for three years, robbing them of time and money and finally plucking them. Such a method of dealing with students is worse than stealing. For in addition to losing both time and money, the young man has a stigma put upon him that sticks through life and is thrown at him by business rivals wherever he may go. A set of teachers that cannot find out sooner than three years whether a student can or cannot learn and whether or not he has natural ability and moral character sufficient to become a member of the medical profession, ought to be "investigated" by the trustees. This ought to be done to determine whether such teachers can impart instruction or are mere talkers against time.

The custom of having a great banquet at the close of the session to be paid for by the students or out of the $25.00 graduating fee, should be relegated to the past. If old men want to get drunk and grow mellow and loquacious they should foot the bill themselves and glorify and mutually compliment each other till they fall under the table if they wish to pass away the night in that way. The student at the end of his career as such, has usually spent all the money he has and all he can borrow. He should not be robbed for the worship of Bacchus.

"Elevate the standard and improve the course of study" is well enough as far as it goes but it is not all. Elevate the public to discriminate between the well trained, thoroughly equipped practitioner and the one who has gained his diploma in the least possible time and with the least possible outlay of brains. Elevate our generous wealthy men to the idea of bestowing their wealth where it will do the most good to the many and not where it will make the most niose and flattering adulation. Elevate the professor, make him a man without reproach—fit to be a teacher. Elevate the student to a proper understanding of his work—the practice of a God-given art, not a mere money getting scheme to be conducted on purely business principles.

Dr. H. S. Houghton says, in a recent number of the New York *Medical Journal*, that one must look upon the patient who has just passed through the third stage of labor as a sufferer of traumatism, has been wounded, and, therefore, her case belongs to the domains of surgery. As the first law of surgery is rest, so the lying-in period is a period of rest, so modified that the patient emerges from it a well and perfectly healthy woman. After the birth of the child, the mother must look forward to a period of six weeks of convalescence devoted solely not only to getting well, but to getting sound and strong. This period is divided into two weeks of absolute rest in bed, one week of alternate resting in bed and moving about the room; the fourth, in gaining the effects of fresh air and sunlight, and the last two in gradually resuming the household duties. By carrying out this plan, as given in detail in the paper, the writer says we may hope to do away with the too frequent evil consequences of childbirth.

The very latest addition proposed to the calendar is "Sanitany Day." This is to be a fixed festival, a given day in May to be devoted to the cult of the goddess Hygeia, and to the pious contemplation of bacteria and kindred topics calculated to make people cheerful, healthy and wise.

Rollo—Tell me, pa, is there any difference between common salt and chloride of sodium? Mr. Holliday—Yes, Rollo, a great difference. Salt is 2 cents a pound at the grocer's, while chloride of sodium is 50 cents a teaspoonful at the druggist's."

TRANSLATIONS.

CLINICAL INVESTIGATIONS REGARDING THE ENLARGED THYROID AND OPERATIONS FOR ITS RELIEF.*

By Prof. Kroelin, (*Zeurich Beitr. z. Klin. Chir.* ix., '92.)

The author had performed the operation for removal of goitre 202 times between the years of 1880 and 1892. Ten of these were done from 1880 to 1884, four of which ended fatally; 181 were cases of a benign character and were performed between the years 1884 to 1892, with three deaths. Among the 202 operations there were eleven cases of malignant degeneration, all of which required grave surgical interference. Five patients died during the operation or directly afterwards. Of the 191 cases of benign tumors three-fourths belonged to the female sex. The indications for the operations are not always for cosmetic improvements, but were frequently due to dyspnœa which, in some cases, were of so grave a character that when seen, the operation was performed almost immediately after. The seven deaths which occurred in 191 cases were caused as follows: One to fatty heart and subsequent collapse; two to suppurative septic mediastinitis; one to bilateral pneumonia; one to marasmus; one to suppurative bronchitis and pneumonia; one was due to the so-called "goitre death" in a tuberculous patient with fatty heart. The operation in seven consisted of total removal; 133 of partial extirpation; four to enucleation and in forty-six the goitre had undergone cystic degeneration; one case to intra-capsular eridement. The author adopted the method of extirpation with careful ligation of each vessel before cutting. Kroelin has carefully studied the symptoms of this disease and arrived at the following conclusions:

The choking attacks often occur in patients suffering from goitre in whom the larynx and vocal cords are normal.

The patients in which the diagnosis of unilateral paralysis of the vocal cords has been made (either partial or complete) may suffer years from dyspnœa but never have an actual choking attack.

Extirpation of the goitre will cure the choking attacks if every portion of the growth is removed that has produced pressure upon the trachea.

This result may be looked forward to with certainty even if paralysis of the vocal cords has been present before the operation.

The paralysis of the vocal cords will remain after the operation while the choking attacks will be cured. Should choking attacks occur after the operation, the cause is not in the larynx but will be found to be due to some external pressure upon the trachea (Recidir der Struma).

Not all goitres pressing upon the trachea will produce acute attacks of choking, since the pressure is sometimes of slow growth and produces a chronic dyspnœa. This form of dyspnœa may gradually become unbearable and the patient die from an increasing poisoning by carbolic acid gas.

The sudden attacks of choking and the so-called "goitre death" can not, however, be explained by the chronic carbonic acid gas intoxication, but there must be an additional reason.

This additional reason is the sudden increase of pressure against the trachea walls by which the contracted space is thoroughly closed.

These sudden increases in pressure are not to be sought in the tumor itself, but are due to certain extraneous surrounding influences which have pressed the tumor as a wedge against the trachea walls.

In mobile or wandering goitres, a certain dislocation of the tumor from a roomy space into a contracted one may sometimes be met with and produce a sort of incarceration, by which the goitre itself does not suffer so much as the more compressible trachea walls.

It is, however, more frequently noticed that the sudden increase of pressure of the tumors is induced by certain mechanisms in respiration, which may be released suddenly and involuntarily. Various respiratory muscles take part in this action. Those of principal importance can be

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

mentioned as the throat and larynx muscles, the sterno-cleido-mastoid, the scaleni, the sterno-hyoid and sterno-thyroid.

The amount of pressure exercised upon the trachea and its resulting attack of choking, is due, first to the strength of the muscular action which pushes the tumor tightly against its walls.

In closing, the author makes the following statement as interesting to those collecting statistics for this operation:

Three patients were deaf and dumb upon whom this operation was performed; three were epileptics; one suffered from diabetes mellitus; six of tuberculosis of the lungs; four were pregnant; six suffered from Morbus Basedorrii.

In all these twenty-eight cases recovery was complete and in no case did a complication arise.

Of particular interest were the results in Morbus Basedorrii in which the recovery was complete.

"Myotomy During Pregnancy."

By Dr. Flaischlen, (*Berlin Cento. Bl. f. Gynæcol.* xvi, 92).

The patient, three months pregnant, was operated upon for the removal of pedunculated myoma. Another was found in the wall of the uterus, which was also removed. The surface of the womb was united by continuous catgut suture. The peritoneal covering of the uterus was united by fine silk sutures.

The patient made a good recovery and at the end of pregnancy gave birth to a living child.

BACTERIOLOGICAL NOTES.

The Anti-Cholera Vaccination.

Klein (*British Med. Jour.*, March 25th, 1893), records the results of his experiments concerning the Hoffkine cholera vaccination. He takes up agar against Hoffkine's method "which supposes that the lesion produced by intra-peritoneal inoculation of the cholera germs is characteristic to that species and that the fact that, under ordinary conditions, the animal dies after such inoculation, proves its specific pathogenic properties, and that if we protect the animal against death from such inoculation the claim may be made that the animal is protected or inoculated against cholera." Klein has repeated Hoffkine's method with six bacilli, viz.: cholera bacilli; vibrio of Finkler; bacillus coli; the proteur vulgaris; the bacillus podigiosus, and the bacillus of typhoid fever. In all cases the injection was followed by distinct illness. The guinea pigs generally die within twenty to twenty-four hours. The lesions produced by the different germs were practically the same. The same fatal results were obtained by injecting (intra-peritoneal) a slightly larger quantity of sterilized culture of these bacteria. "As only the bacteria themselves were used (scraped from the surface of agar cultures) for the injections it follows that all these six species of bacteria contain in their protoplasm a poisonous principle, which appears to be the same for all species, since the disease produced and the anatomical changes found on *post-mortem* examination were the same." The author found that smaller non-lethal doses (one-fifth to one-tenth of a culture) injected into the peritoneal cavity of guinea pigs produced temporary illness, and after recovery they were found to be refractory to otherwise fatal doses of the same species of bacteria. This condition was produced by the injection of non-lethal doses of both the living and sterilized cultures. The most interesting point was, that a guinea pig that was made immune to any one of these six bacilli (by intra-peritoneal injections of non-lethal doses) was also immune to any one of the others; for example, a guinea pig that was made immune or refractory to the *proteus vulgaris* was also immune to Asiatic cholera. He also found that repeated subcutaneous injections would render the animals refractory to the intra-peritoneal injection of an otherwise fatal dose.

Klein concludes that these six bacilli contain the same poisonous substance in their cellular protoplasm but it must be

carefully distinguished from the substances (ptomaines, specific toxins, etc.), which are elaborated by them in nutritive media including the animal body. These differ (*a*) from one another; and (*b*) from the intra-cellular poisons. The intra-peritoneal inoculation increased the virulence of the different bacteria as indicated by Hoffkine for the cholera germ. He also found, "that guinea pigs that were made refractory by the intra-cellular poisons were not immune to the specific toxines or against the growth and multiplication of the bacilli and the production by them of their specific toxines in that refractory body." [This fact, if sustained, demolishes to a great extent the anti-cholera vaccination as set forth by Hoffkine. The work is also of much value on account of the similarity of the results to those obtained by Roux and Rodet by intra-peritoneal injections of the typhoid and coli bacteria by which they attempted to prove the identity of these two species of bacteria. We now have evidence that at least six species of bacteria will produce the same results and, consequently, the relationship established by Roux and Rodet between the coli and typhoid bacilli does not hold. The results obtained by Dr. Klein should cool the over-enthusiasm which is being manifested in some places with reference to cholera-vaccination until more is learned of the method than is now known.—Ed].

The Purification of Drinking Water by Sand Infiltration; its Theory, Practice, and Results.

Sedgwick (*Journal of New England Water Works Association*, Vol. VII., No. 2), gives a full account of our present knowledge of sand filtration of drinking water. It is humiliating, but it is true, that the sanitary condition of many of our otherwise excellent water supplies is to-day discreditable to American Science, American engineering and American civilization. "So long as the water supplies of important cities like Chicago, Albany, Lawrence and St. Louis remain in their present condition so long will they constitute a blemish upon our fair civilization." It matters not how wonderful the tunnels, or how magnificent the pumps of any water works, if they convey to the confiding citizen the deadly germs of disease they must be considered failures.

Heretofore the selection of the sources of water supply has been influenced by the belief that impure water quickly, naturally and effectively purifies itself. It can no longer be claimed that the dangers of polluted drinking water are doubtful or imaginary. The purification of water from a sanitary standpoint is the most difficult kind of purification. The principal natural methods contributing to the sanitary improvement of water are *sedimentatives, storage* and *filtration*. Light, temperature, pressure and electricity have their effects, but an impure water is purified in nature chiefly by settling, for the bacteria have weight, and at least in some stages of their development, tend to settle.

Storage has an immense sanitary value. When allowed to stand some of the bacteria settle to the bottom and eventually perish; some are destroyed by light, but the disease germs, which are in water apparently somewhat short-lived, perish. It is also a fact that living bacteria largely disappear in the pipes of a service. To these facts we must look for the explanation of the limited infectiousness in some cases by water obviously badly polluted with raw sewage.

The natural method, which is more common and more trust-worthy, is *filtration* through the earth or sand. The sand filter was first introduced in England in 1839. This method is used most extensively in European cities, and the results that are obtained in comparing the death rate, from germ diseases, of the cities which use the sand filter and those which do not, are sufficient to guarantee its success.

The final conclusions reached by Dr. Sedgwick are: (1) *Every surface water before it is used for drinking purposes should be freed from all infectious substances.*" (2) *For this purpose, whenever large quantities of water are to be treated, sand filtration is at present the most convenient and effective method.*

Dispensary Physician. — "Take this medicine three times a day after each meal."

Dispensary Physician.—"What?"

Dusty Rhodes.—"The-er-meal ticket. —*Puck*.

The Bacillus Coli Communis in Inflammatory Affections of the Anus.

A very interesting series of observations have been made by Hartmann and Lieffering (*Bull. de la Soc. Anat.* No. 3, 1893) on the pathogenic effect of the coli bacteria in the causatives of hemorrhoidal phlebitis and of some forms of perineal abscess. Their opinion is based upon the results of a careful examination (microscopical) of sections of blood-clots, and also cultures of blood taken from an inflamed external hemorrhoid.

The preparations made by the authors indicate that the inflammation is the result of the penetration of the coli bacteria into the affected pile as these bacteria could be seen in great numbers in the section of the clot and in cultures from the blood. On the other hand cultures made from the blood of non-inflamed piles remained clear. It has long been recognized that a painful and swollen condition of the external pile was the result of a phlebitis, and due to coagulation dependent on inflammation of the coats of the veins, but heretofore there has been much doubt as to the primary cause of the inflammation.

The Etiology of Emphysematous Cellulitis.

Frænkle (*Centralblatt f. Bakteriologie u. Parasitenkund*, xiii., Vol. 1, 1893), announces the result of a careful investigation into the cause of four cases of this affection. From the bacteriological examinations he was able to isolate the same bacillus from each case. In appearance it resembles somewhat closely the bacillus of anthrax. In is non-motile, anærobic and produces gas when grown under anærobic conditions. (The gas is supposed to be identical with that in the tissue though no analysis was made). No spores have been observed. Its pathogenic effect was determined by the subcutaneous inoculation of guinea pigs. It produced extensive cellulitis with gas. In the original cultures the bacillus was associated, in three or four cases, with pyogenetic cocci.

[It should be observed that this germ differs very considerably from the gas-producing germ found in the blood vessels, by Prof. Welch and Dr. Nuttall (*Bulletin Johns-Hopkins Hospital*, 1892, p. 81) and is undoubtedly a different species.—Ed].

ABSTRACTS.

THE PROTEOLYTIC ACTION OF PAPOID.

The juice of the papaw has long been known to possess the power of dissolving and digesting proteid matter. At one time, this peculiarity was looked upon as something quite unique, but in recent years other like ferments have been discovered in the vegetable world, and to-day several proteolytic ferments of vegetable origin are more or less widely known. Curiously enough there is nearly always associated with the proteid-dissolving ferment, a rennet-like ferment, just as we find the two ferments associated in animal secretions. Thus, in gastric juice, pepsin and rennet are close allies and companions, and similarly in the papaw a proteolytic ferment and rennet-like ferment are associated either in the form of a single substance endowed with the two functions, or more probably as two closely related enzymes.

Papoid, a preparation from the papaw plant, has the power of digesting to a greater or less extent all forms of proteid or albuminous matter, whether coagulated or uncoagulated. Furthermore, papoid is peculiar in that its proteid-dissolving power is manifested in a neutral, acid and alkaline medium. To be sure, the proteolytic power of the ferment is not quantitatively the same under the above three distinct conditions, but it is plainly manifest in acid and alkaline solutions, as wel as in a neutral fluid, provided of course the percentage of acid or alkali is not too large. With coagulated proteids, as cooked beef proteid, the highest digestive power is obtained in the presence of 2–4 per cent. sodium bicarbonate. The relative ferment action in the presence of acids and alkalies is well exhibited in the following series of experiments with coagu-

lated beef proteids.

The beef proteids used were prepared by passing lean beef through a hashing machine, washing it thoroughly with water until all blood was removed and it had become nearly white in color, after which it was completely coagulated by being boiled in water, and then pressed as dry as possible. So prepared 10 grams of the beef proteids contained 3.7438 grams of dried proteid (dried at 110° C.)

Each digestive mixture contained 0.5 gram papoid, 10 grams of the prepared beef, and 25 c. c. of water in which were dissolved the indicated percentages of acid and alkali.

The digestions were warmed at 45° C. for five and a half hours, with frequent stirring, after which the undigested residues were filtered off on weighed filters previously dried at 110° C. The undissolved matter was next washed with hot water until all soluble products were removed, then dried at 110° C. until of constant weight.

From these results it is manifest that papoid will digest and dissolve cooked beef proteids with a fair degree of readiness, and further that the ferment acts most energetically in the presence of 2–4 per cent. sodium bicarbonate, while a slight addition of acid increases the solvent action a trifle over that of the neutral solution. Hence, papoid is peculiar in that it will digest proteid matter in a neutral fluid, in this respect resembling trypsin, the proteolytic ferment of the pancreatic juice. But trypsin is a ferment associated with an alkaline secretion, and as a proteolytic agent acts to advantage only in alkaline fluids. Papoid agrees with trypsin in so far that its proteolytic action is increased by the presence of an alkaline medium, in some cases greatly increased by the presence of 2–4 per cent. sodium bicarbonate. On the other hand, the action of papoid in a neutral solution is increased by the addition of very small amounts of hydrochloric acid, and in some cases the increase is very marked.

Another action to be noted as characteristic of papoid digestion is the peculiar change it produces in the proteid acted upon. The exact character of this change is dependent upon the condition of the proteid and, in part, upon the character of the medium in which the digestion is carried on. Thus, with a coagulated proteid, as cooked beef, there is a rapid disintegration and falling apart of the proteid into tiny fragments, until at last the undigested matter has the character of a pultaceous residue. Hence, in this respect papoid resembles trypsin. This peculiarity is especially noticeable in the digestion of cooked beef, or boiled blood-fibrin, with papoid in the presence of 0.1 per cent, and 0.2 per cent. hydrochloric acid. The natural tendency of the acid under such circumstances, especially at 45° C., is to cause the beef fibres to swell up, but this tendency is gradually counteracted by the presence of papoid and eventually, but more slowly, there comes about the same disintegration of the proteid seen in a neutral or alkaline solution. With a raw, or non-coagulated proteid, on the other hand, there is at first, especially in an alkaline solution (sodium bicarbonate) a softening action, which is in great part independent of the alkali; followed it may be, by the formation of an almost solid homogeneous, jelly-like mass, in which the fibres lose their individuality, thus differing from the swelling produced by the alkaline fluid alone. As digestion proceeds, the jelly-like mass gradually becomes thinner from the secondary or solvent action of the ferment. The same softening, though less pronounced, shows itself with a neutral solution of papoid, followed by more or less disintegration, although the residue never takes on the appearance seen in the digestion of a cooked proteid.

Another point characteristic of papoid is its ability to act in the presence of a small amount of fluid; indeed, its best and characteristic action is seen only when a small volume of fluid is present. In this respect it differs very markedly from the animal ferment pepsin, and for this reason any direct comparison of the two ferments is practically impossible, since they act best under such widely different conditions.

Still another peculiarity of papoid is its great resistance to the ordinary destructive action of high temperatures. Animal ferments, especially those concerned in the ordinary processes of digestion, act most energetically, as is well known, at approximately the body temperature. Raising the temperature to near 60° C. quickly brings about a diminution in digestive action, followed by a gradual de-

struction of the ferment. Lowering the temperature below that of the body is likewise accompanied by a diminution in digestive action, although ordinarily less marked than the inhibition caused by a rise of temperature. With the animal proteolytic ferments pepsin and trypsin, digestion is very slow at, say 20° C. With diastase, the vegetable amylolytic ferment, the most rapid conversion of starch into sugar takes place at about 55° C.

A study of papoid digestion with reference to the influence of temperature on the rate of proteolytic action has shown several very interesting results. Thus, in an acid solution (boracic acid) a larger amount of cooked beef proteids is dissolved at 70° C. than at any lower temperature, while even boiling the ferment solution fails to destroy entirely the action of the ferment; a fact which is especially true of an alkaline (sodium bicarbonate) solution of papoid. Furthermore, at a comparatively low temperature, 20° C., digestion is very pronounced in both a neutral and acid solution of the ferment, while in an alkaline fluid digestive action is almost as great at 20° C. as at 45° C.

The three series of experiments illustrative of these points, were made at the same time and under exactly the same conditions, excepting the specified variation in temperature and reaction. Each digestive mixture contained 0.5 gram papoid, 10 grams of prepared cooked beef (equivalent to 3.5538 grams of dry proteid) and 25 c. c. of fluid; the latter consisting of water alone in the neutral series, of 2.0 per cent. boracic acid in the acid series, and of 2.0 per cent. sodium bicarbonate in the alkaline series. The digestions were continued at the given temperatures for six hours, the fluid itself being brought to the required temperature before the proteid was added.

We notice in these results that in an acid solution (boracic acid), papoid is slightly more active than in a neutral fluid, while in an alkaline solution (sodium bicarbonate) the activity of the ferment is increased very greatly; and further, that this relationship holds good practically for all temperatures. The most striking facts, however, brought out by these experiments are: first, the marked activity of the ferment at the comparatively low temperature of 20° C. (the temperature of the room at the time the experiment was tried), especially in an alkaline fluid; and secondly, the retention of proteolytic power after the solution of the ferment has been actually boiled. Here, too, the alkaline solution appears to exert a certain protective influence upon the ferment, which is difficult to explain. Certainly, sodium bicarbonate alone will not dissolve a coagulated proteid to any great extent, as has been demonstrated in connection with other experiments. Hence, we are forced to the conclusion that in an alkaline fluid especially, papoid is extremely resistant to the inhibitory effects of low and high temperatures, so characteristic of most known ferments. This being true, it is obvious that papoid in the presence of sodium bicarbonate possesses special advantages in cases where it is desired to soften or digest tissue or other proteid matters, at comparatively low temperatures. At the same time, as before stated, it is a ferment very resistant to the ordinary destructive effects of high temperature, and is especially characterized by exhibiting its maximum digestive power at about 70° C.

The mere fact that papoid exerts a certain amount of solvent action on proteids does not necessarily imply a true digestive action akin to that of the ordinary digestive ferments. As is well known, the latter agents exert their solvent action by virtue of certain chemical changes they induce, as a result of which new and for the most part soluble products result, of of which the proteoses, or albuminoses, and peptone are the principal representatives. It is to be presumed, however, that papoid acts in a similar manner. Indeed, Martin long ago pointed out that the proteolytic ferment of papaw juice, acting on blood fibrin, formed large quantities of peptone, together with leucin and tyrosin, as products of its digestive action. Such experiments as I have tried bearing on this point clearly show that the proteid-dissolving power of papoid is due to a genuine ferment action, whereby soluble products are formed, which, so far as ordinary chemical reactions show, are closely akin to, or identical with, those formed in gastric and pancreatic digestion. Leucin and tyrosin are likewise formed, thus showing in another way the resemblance of this ferment to the trypsin of the pancreatic juice.

While, in a general way, the final pro-

ducts of papoid digestion are essentially the same under all ordinary circumstances, certain differences appear in the primary or side-products, coincident with changes in the reaction of the digestive fluid and in the nature of the proteid undergoing digestion. Some of these points may be briefly summarized.

In the digestion of coagulated egg-albumin with an alkaline (2 per cent. sodium bicarbonate) solution of papoid, even when the digestion has been long continued (say 18 hours) at a favorable temperature, and the ferment solution strong, there invariably remains a fairly large undissolved residue. At first glance this might be considered as a residue of unaltered coagulated albumin. On being tested, however, it is found soluble, in great part at least, in warm 0.2 per cent. hydrochloric acid, from which solution it is precipitated by addition of 0.5 per cent. sodium bicarbonate, and redissolved by an excess of the alkaline fluid. This residue is, likewise, directly soluble in warm 0.5 per cent. sodium carbonate, and is precipitated by neutralization. These two reactions clearly indicate that the above residue cannot be composed of unaltered coagulated albumin, since this substance is wholly insoluble in dilute acid and alkali. The only plausible inference, therefore, is that the so-called insoluble residue in this case is composed of an albumose-like body, insoluble in 2.0 per cent. sodium bicarbonate; a possibly primary or side-product of the papoid digestion of coagulated egg-albumin. It is evidently a somewhat unique body, differing from heteroalbumose, and from ordinary globulin, by being soluble in salt solution. Aside from this peculiar insoluble body, the other products of digestion isolated were deuteroalbumose, a fairly large amount of peptone and some leucin and tyrosin.

In the digestion of raw-blood fibrin with a neutral solution of papoid, a somewhat different condition of things was observed. The undissolved residue contained, perhaps, a small amount of the body so characteristic of the digestion of coagulated egg-albumin but certainly not a large amount. The clear filtered digestive fluid, however, gave evidence of the presence of a peculiar body which was wholly wanting in the digestion of the coagulated albumin. Thus, the addition of water to the clear neutral fluid gave a heavy white precipitate of what was later proved to be an albumose-like body, readily soluble in a little 10 per cent. salt solution. Addition of 0.2 per cent. hydrochloric acid, likewise, produced a heavy white precipitate of the same body, easily soluble in a slight excess of acid. Boiling the neutral solution also gave rise to a heavy precipitate or coagulum, apparently the same body as that precipitated by water and by dilute acid, slowly but completely soluble in warm 0.2 per cent. hydrochloric acid and in warm 0.5 per cent. sodium carbonate solution. Hence, this body is a soluble albumose and not a coagulable globulin. It is completely precipitated from a neutral solution by heat, and partakes of the general character of heteroalbumose, being insoluble in water but completely soluble in salt solutions, as well as in dilute acid and alkali. In addition to this peculiar primary body, there was also found a large amount of more soluble primary and secondary albumoses, together with true peptone, leucin and tyrosin.

In the digestion of cooked beef proteids with a neutral solution of papoid, as likewise with an alkaline solution of the ferment, the peculiar heteroalbumose-like body above described was wholly absent; only the ordinary primary and secondary albumoses were observed, together with a large amount of peptone and some leucin and tyrosin.

From the above results, it is plainly evident that the power possessed by papoid of dissolving various forms of proteid matter is dependent upon an ordinary digestive action akin to, or identical with, that of digestive ferments in general, whether animal or vegetable.—Prof. Chittenden in *Dietetic and Hygienic Gazette.*

Mother.—My daughter is tongue-tied and I fear her entire future is ruined.

Doctor.—Don't worry, madam. There'll be dozens of widowers only to glad to marry her.

Tramp. "Say, mister, don't you want to give me somethin' to do?"

Merchant. "You! Nonsense; what can you do that would be of the least value to me?"

Tramp. "Well, I'd move on for a dime."

EPISTAXIS.

Undoubtedly plugging the nares by aid of Bellocq's cannula, says Dr. Philips, is an excellent method, but occasionally, especially in country practice, a Bellocq's cannula is not at hand, and some method easy, effectual and effected by material always within reach, must be resorted to. Such a method I have found in the following: A piece of old, soft thin cotton or silk, or oiled silk, about six inches square (a piece of an old handkerchief will answer) is taken, and, by means of a probe, metal thermometer case, or penholder, or anything handy, is pushed centre first, "umbrella fashion," into the nostril, the direction of pressure when the patient is sitting erect being backward and slightly downward. It is pushed on in this fashion until it is felt that the point of the "umbrella" is well into the cavity of the naso-pharynx. The thermometer case or probe, or whatever has been employed, is now pushed on in an upward direction and then towards the sides, so as to pull more of the "umbrella" into the naso-pharynx. The thermometer case is now withdrawn. We have now a sac lying in the nares, its closed end protruding well into the pharnyx behind, and its open end protruding at the anterior opening of the nares. If it be thought necessary, and is convenient, the inside of the sac may be brushed with some household astringent, such as alum solution, turpentine, etc. A considerable quantity of cotton-wool is now, by means of the thermometer case, pushed well back to the bottom of the sac. Then the thermometer case being held firmly against the packed wool, the mouth of the sac is pulled upon, and thus its bottom with the wool packed in it is pulled forward, and forms a firm, hard plug wedged in into the posterior nares. We may now pack the sac full of cotton-wool, dry or soaked in some astringent solution. The mouth of the sac may now be closed by tying it just outside the nostril with a piece of strong thread; it is then trimmed with scissors and the ends of the thread secured outside.

The above method is easier than any I know when both nostrils have to be plugged. It might be suggested to oil the cotton or silk in order to render its introduction easy and to prevent it adhering to the mucous membrane, and to render it easy of removal; but I have never found any difficulty without the oil, as the blood renders the material wet and easy of introduction, while the oil does not facilitate removal, and may modify the effect of the astringents that may be used. The plug may remain *in situ* as long as any other nose plug. In removing the plug open the mouth of the sac, and with small dressing forceps remove the cotton-wool bit by bit; if there is bleeding, simply syringe the sac with weak carbolic lotion or Condy's fluid and repack with clean cotton-wool, or wool impregnated with some antiseptic. If there is no bleeding when the wool is picked out, gently pull out the sac; or if it be adhering to the mucous membrane, syringe in a little warm water, and it may then easily be removed. This method has many advantages. (*a.*) It is easy, quickly accomplished, and effectual, and the materials are to be found in every house, and indeed, about everybody's person (I have plugged in this manner, simply using a handkerchief, one part of which was used for the sac, and the other torn into narrow strips in place of the cotton-wool). (*b.*) No damage is done to the floor of the nose or back of the soft plate by strings, etc.; (*c.*) no disagreeable hawking, coughing or vomiting takes place while the plug is introduced; (*d.*) there are no dissagreeable strings left hanging down the throat, causing coughing or sickness while the plug is in; (*e.*) the plug can be removed gently without any force, so that no damage is done to the mucous membrane and no return of hemorrhage caused. I employed this method frequently when in country practice, and do so now in bleeding after operation on the nares, and have always found it to be satisfactory. As the method has been of great use to me, and as I am not aware that anyone has spoken of it before, I take the opportunity of mentioning it, in the hope that it may be of some use to some brother practitioner when confronted by an urgent case of epistaxis, and other means of plugging are not at hand.

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOURNAL OF THE MEDICAL SCIENCES

For May, contains a paper by Dr. Willian B. Coley, on

The Treatment of Malignant Tumors by Repeated Inoculations of Erysipelas.

In his paper the author presents the report of ten cases treated by him and in addition he has collected and tabulated all the reported cases of carcinoma and sarcoma in which erysipelas, either spontaneous or artificial, intervened. His conclusions are based upon a careful study of these cases as well as the practical experience derived from his own observations. The close resemblance of cancer to other diseases known to be of bacterial origin is discussed and the work of Sir John Simon in pointing out this analogy is referred to. The author considers that hereditary influence only supplies the *predisposing conditions* in cancer as in tuberculosis. "There is," he says, "a growing tendency to no longer adhere to the stereotyped classification of 'tumors,' and we venture to perdict that in the near future, instead of 'tumors,' a class at present embracing elements without the remotest analogy either in their etiology or mode of development, we shall have two main groups—the first of which might be designated as *congenital hypertrophies*; the second, *neoplasms*, etiologically dependent upon infection from without." The analogous diseases in animals and plants also receive due attention from the author and he refers to the fact that the "galls" on trees have been proved to be of parasitic origin and that "coccidial infection" in animals presents an analogy so striking that many observers have considered it identical with cancer. He offers the following explanation of the influence of erysipelas on malignant tumors: "If a small quantity of blood serum of an animal rendered immune to tetanus is capable of destroying or rendering inert the virulent bacilli in a fresh case, it is quite easy to understand that the toxic products of the erysipelas streptococci might bring about such changes in the blood-serum as to destroy the parasite of cancer. The parasite having been destroyed, the irritation would consequently cease, and this would lessen the hyperæmia on the parts, upon which factor the life of the tumor-cells of low vitality depends." So far as the author is aware, his cases are the only ones that have been treated by repeated injections of the pure fluid culture of erysipelas. The doses employed have varied with the age and virulence of the culture but he has aimed to obtain a good reaction, a temperature of 104° or 104½° frequently following. The effect upon the tumors was more marked in the cases of sarcoma than carcinoma, but all cases showed a cessation of growth and a more or less marked diminution in size. The results from an attack of true erysipelas have been far more brilliant and permanent. In view of these results the author thinks it may be considered proven that a portion if not all, of the benign influence rests in the toxic products of the erysipelas germ rather than in the germ itself. The dangers associated with erysipelas also receive due consideration and the author presents the following conclusions:

1. The curative effect of the erysipelas upon malignant tumors is an established fact.
2. The action upon sarcoma is more powerful than upon carcinoma, in about the ratio of 3 to 1.
3. The treatment of inoperable malignant tumors by repeated inoculations of erysipelas is both practicable and not attended with great risk.
4. The curative action is systemic, and probably due chiefly to the toxic products of the streptococcus, which products may be isolated and used without producing erysipelas.
5. This method should *not be employed indiscriminately* until further experiments have proved its limitations.

In a foot note added since the above article went to press the author reports a fatal case of erysipelas following inoculation—a large inoperable sarcoma of the neck.

Dr. Egbert H. Grankin presents

A Clinical Contribution to the Subject of Symphysiotomy.

The author sounds a note of warning lest the profession be carried away by the "symphysiotomy wave" which is sweeping over the country and which may be followed by the same abuses as the "abdominal section wave" of a few years ago. The author holds that "at present it may fairly be claimed that symphysiotomy should not have a mortality rate, where it is resorted to on a patient not exhausted by protracted labor, or by ineffectual attempts at delivery by other means and on a patient not septic. Other things being equal, further, the child should be saved. Injury to the bladder and urethra is avoidable. Hemorrhage is only likely to occur where an improper incision has been made, and if it do occur it may be controlled. Sepsis here, as elsewhere in surgery, means faulty technique. His experience leads him to favor a primary incision extending upward from the pubic eminence. He regards the downward incision, to one side or the other of the clitoris, as faulty and unnecessary. He also believes it is better to avoid where possible the cutting of the insertion of the recti. The finger should be inserted between the recti, and when hooked under the symphysis, should remain there in order to guard the bladder and urethra from injury. The incision through the symphysis should be made from above downward, and from without inward. The subpubic ligament should be severed by cutting down on the finger. In the average case a stout bistoury will suffice for the operation. The subpubic ligament must be severed in order to secure the separation at the symphysis

which leads to increase in the pelvic diameters. When bringing the bones in apposition, after delivery, especial care must be taken to depress thoroughly the uretha and vesical neck else these will be nipped and a vesico-abdominal fistula result. The author reports the following cases:

CASE I. 19 years old; primipara at term. Forceps were applied ineffectually. Version was contraindicated. The pelvic measurements were:

Spines	$8\frac{3}{4}$	inches.
Crests	$9\frac{3}{4}$	"
Antero-posterior, about	7	"
Conjugata vera (under chloroform)	$3\frac{1}{4}$	"

The diameters of the fœtal head were:

Bi-temporal	3	inches.
Bi-parietal	$3\frac{1}{2}$	"
Sub-occipito-bregmatic	$3\frac{3}{4}$	"
Occipito-frontal	$4\frac{3}{8}$	"
Occipito-mental	5	"
Circumference	$13\frac{3}{4}$	"
Weight of child (a female)	7.1	lbs.

Two days after delivery a deep and extensive sub-mammary abscess was opened. On the seventh day a mural abscess broke through the line of incision; on the tenth day a vesico-abdominal fistula appeared; and later a catarrhal laryngitis and a double crural phlebitis. The fistula closed spontaneously; the patient was first out of bed on the fifteenth day, and walked for the first time on the thirty-fifth day. There exists close union at the symphysis, and no mobility.

This woman could only have been delivered otherwise of a living child by the Cæsarean section and symphysiotomy was elected in order to avoid stillbirth and embryotomy of the living child. The child might have been dragged through by forceps, but dead and at the expense of the maternal soft parts.

CASE II. 23 years old; primipara. Efforts at inducing premature labor had been made without success. The pelvic measurements were:

Spines	$9\frac{1}{2}$	inches
Crests	$9\frac{3}{4}$	"
Antero-posteior	$6\frac{3}{4}$	"
Conjugata vera (under chloroform)	3	"

The measurements of the fœtal head were as follows (the child being premature by about four weeks):

Bi-temporal	$2\frac{5}{8}$	inches
Bi-parietal	$3\frac{3}{8}$	"
Occipito-mental	$4\frac{7}{8}$	"
Occipito-frontal	$4\frac{1}{8}$	"
Sub-occipito-bregmatic	$3\frac{3}{8}$	"
Circumference	13	"
Male child, weighing	5.1	lbs.

The convalescence of the patient was uneventful. The author concludes that under the new order of things he is obliged for the present to look upon symphysiotomy as an operation bidding fair to displace the Cæsarean section under the relative indication.

Dr. Roswell Park discusses the subject of

Pseudarthrosis

(Including all varieties of delayed and non-union).

I. Simple delayed union; which may be caused by shock, old age, rhachitis, gestation, lactation, scrobutus, syphilis, cancer, paralysis, local unrest.

II. Complete separation; detachment of fragments; non-union. May be due to the above causes, faulty fixation, interposition of soft parts. The bone ends may be variously altered.

III. Fibrous union. With or without much deformity.

IV. Osteophytic pseudarthrosis. May be connected with tuberculosis, syphilis, cancer, hydatid cysts, etc.

V. Fibro-synovial—true new joint.

The surgical treatment of the condition is carefully considered under the following heads:

1. Stimulation without penetration of the bone. 2. Stimulation and irritation of the seat of fracture by something introduced from without. 3. Exposure of the parts and mechanical fixation. In the paper thirteen cases are reported illustrative of the subject.

Dr. Edward Blake contributes a paper entitled "Neuroses and Arthropathies: are they related?" in which he seeks to establish the following: 1. That there is a relation between chorea and chrondritis. 2. That the nexus which unites them is a common causation. 3. That the relationship is not confined to chorea and chondrosis, but that it exists with regard to the neuropsychoses and all the arthropathies generally.

Alexander McPhedran, M. B., and John Caven, M. D., L. R. C. P. Lond., contribute the report of a case of "Diffuse Tubercular Hepatitis with Tubercular Pericarditis." Dr. Harry Friedenwald discusses the subject of "Cranial Deformity and Optic-nerve Atrophy," presenting a tabulated report of cases from various observers. George Heaton, M. A., M. B. Oxon., F. R. C. S. reports "A Case of Cerebral Abscess following the operation of Trephining for Compound Depressed Fracture of the Skull; Drainage of the Abscess; Recovery." Dr. John B. Roberts contributes a paper on the "Cure of Complete Prolapse of the Rectum by Posterior Proctectomy." Dr. W. Page McIntosh reports a "Laparotomy and Removal of Cystic Tumor (cysto-adenoma) of the Peritoneum; Formation of Artificial Anus; Subsequent Laparotomy and Resection of the Colon; Closure of the Artificial Anus, Recovery."

THE MEDICAL CHRONICLE

Of Manchester, England, for April, contains an exhaustive paper by Dr. Graham Steell on "Heart Failure as a Result of Chronic Alcoholism." The paper is a thorough discussion of the subject into which the author enters minutely, illustrating the various points by tracings from the shygmograph. Dr. Patrick Hehir contributes an article on "The Hyderabad Chloroform Commissions" in

which the work done and the results published by the commission are reviewed. The author was the president of the second commission. The article contains nothing additional to the published findings of the commission. In the department of "Clinic," Dr. Thomas Harris reports a "Tumor (angiolithic sarcoma) of the Dura Mater compressing the Motor Area of the Cortex of the Right Cerebral Hemisphere." Clinically, one of the most interesting features was the complete absence of any convulsions, unilateral or otherwise, until the slight convulsive attack which immediately preceeded death. Another point of special interest in reference to cerebral surgery is the fact that although at the post-mortem examination the tumor was so large, and had compressed and displaced so much brain substance, that complete recovery of power over the left arm and leg could not have been hoped for; yet, had the growth been submitted during life to surgical interference, it could have been removed. It was sharply circumscribed, could have been shelled out, and the surrounding brain substance was neither infiltrated with growth nor softened, as is so frequently seen around cerebral tumors.

Pathologically the growth is of interest from the microscopical structure, especially on account of the hyaline changes which the blood vessels showed, and the subsequent deposition in the tissue, which obliterated the vessels of crystalline salts. The growth appears to correspond somewhat closely to what Cornil and Ranvier describe as an angiolithic sarcoma.

Dr. Judson S. Bury reports "A Case of Cortical Tumor involving mainly the First Left Frontal Convolution." The alleged cause of the symptoms was a blow on the head.

Both these reports are illustrated by woodcuts showing the location and relations of the tumors reported.

THE AMERICAN JOURNAL OF OPHTHALMOLOGY.

Especially well timed and important is a paper in the March number by Dr. Ayres on the

Conservative Treatment of Strabismus Convergens.

After briefly reviewing the history of tenotomy of the internal rectus as proposed by Stromeyer in 1838 and first successfully executed by Dieffenbach in 1839, Dr. Ayres refers to Donders and his great work on the "Anomalies of Refraction and Accommodation of the Eye." In it Donders states that "Strabismus Convergens almost always depends upon hypermetropia, and in discussing the origin of strabismus says that it is promoted by circumstances which render convergences easier, and mentions a peculiar structure or innervation of the muscle. The former cause was better known to him than the latter, and it is possible that he attributed too much to it, as the latest investigations tend to show that the innervation of the muscles is a very important factor." In support of this statement the author quotes Noyes, Stellwag, Grut and others. He next discusses the treatment of a case of "Convergent Strabismus beginning in early life from the second to the fifth year" by correction of the ametropia. He concludes thus: "In my judgment, except in very high degrees of squint, it is better for the child to wear the correcting lenses for a period of from one to four years before a tenotomy is made. This may seem very conservative, but I think that *final* results will bear me out in this position. The primary results of many skillfully made tenotomies are very satisfactory for a period of five years or even longer. But examine these cases later on and what do you find? A moderate and even a pronounced divergence. Can we avoid this result? Stellwag speaks of persons who outgrow strabismus, and every oculist has seen them. Does this not prove that there is a want of muscular balance which has a tendency to correct itself as the child develops into manhood or womanhood? This is the factor which tends to bring about the bad results which we used to see so frequently some years ago." But after trial of proper glasses for a reasonable period and in children from ten to fifteen years there remains a quota of cases requiring operation, in speaking of which the writer says: "I feel quite safe in asserting that the profession has belittled the importance of strabismus operations. It requires much skill and judgment to do them successfully, and many important points have to be considered before determining the propriety of the operation."

A Case of Gumma of the Sclerotic

is reported by Dr. Adolf Alt. It occured in a married woman, thirty five years old, and manifested itself as a small swelling, situated near the corneal margin up and inwards. About two weeks after she was first seen she had a swelling on the pre-auricular glands and sore throat, and finally a papulous syphilide made its appearance all over her body. Mercury was given internally, but no local application which he used seemed of any value in treatment of the scleral growth until he made inspergations of calomel under which "the tumor shrank rapidly."

THE DUBLIN JOURNAL OF MEDICAL SCIENCE

First place is given in the March number to Dr. Stoker's paper.

On the Operative Treatment of Trifacial Neuralgia.

Although the points spoken of are purely surgical, they will, in view of the frequent failure of medical treatment in neuralgia, recommend themselves to physicians no less than to surgeons. The suffering produced by some forms of trifacial neuralgia are so great, the malady is so common, and generally so intractable, that any contribution to its literature will be welcome alike to physicians and surgeons.

The doctor discusses quite fully four meth-

ods of treatment—neurotomy, neurectomy, stretching, and avulsion. The following summary of the paper may thus be briefly stated:

1. That in cases of trifacial neuralgia demanding operative treatment neurotomy is not usually a satisfactory or efficient operation.

2. That in purely sensory nerves stretching is at best but a temporary expedient, and either should not be undertaken, or having once performed and followed by a return of pain, should not be repeated.

3. That the reasonable treatment in trifacial neuralgia of an extreme character is neurectomy, and that while the operation on divisions of the 5th nerve external to the cranial cavity may be regarded as an established procedure, the ultimate operation of removing the Gasserian ganglion must still be considered as on its trial.

4. That avulsion should only be practiced as a part of an open operation, and that, as originally proposed by Professor Thiersch, it should be regarded as a blindfold and unscientific proceeding, to be undertaken only when an open operation is for sufficient reasons impossible or inexpedient.

Movable Kidney

Is the subject of Dr. Kendal Frank's paper which is carefully prepared and will be found very instructive. He takes Newman's classification of displacements of the kidney as the most convenient division for study, dividing them into three classes:

1. Simple displacement, without mobility of the kidney.

2. "Movable kidney," where the organ is perceptibly mobile behind the peritoneum.

3. "Floating kidney," where the peritoneum forms a mesonephron which attaches the kidney loosely to the spine.

Four methods have been employed for fixing the kidney in the loin.

M'Cosh thus summarizes them:—

1. The sutures may be passed through the adipose capsule alone.

2. They may be passed through the fibrous capsule of the kidney itself.

3. They may be passed through the parenchyma of the kidney.

4. The fibrous capsule may be partially stripped off the kidney in order to obtain a surface of renal tissue, by means of which the adhesions, it is believed, would be firmer. The sutures are then passed through the parenchyma and capsule, just inside the border of the raw surface. This is the method recommended by Jordan Lloyd.

Of these various methods it would appear that the best results are obtained when the parenchyma of the kidney is included in the suture, or when the capsule is partially stripped off.

Of the material for suture, catgut has been practically discarded on account of its becoming absorbed before the adhesions have become sufficiently strong to retain the kidney *in situ*. Kangaroo tendon has been proved reliable in the hands of Gould and Morris. Aseptic boiled silk has been used by Keen in his cases, and "it has answered admirably."

The wound in the loin is generally healed in eight to ten days; but it is advisable to keep the patient in bed in the horizontal position for a much longer period—about six or seven weeks—so as to afford time for the adhensions to become firm.

By these means a complete cure can be obtained, and the kidney be firmly secured into its normal position.

Three other papers, "The Influence of Public Cleansing on the Mortality of Towns," by Dr. Finn; "The Treatment of Pulmonary Consumption in Special Hospitals and Dispensaries," by Dr. Denham. "Some Recent Clinical Experiences," by Dr. Moore completes this issue.

SELECTED FORMULÆ.

Tertiary Syphilis.

Dr. Jos. Jones speaks highly of the following:

℞

Hydrarg. biniod.,	gr. iv.
Kal. iodid.,	ʒj.
Tr. iodin.,	ʒj.
Syr. iodid. ferr.,	ʒj.
Aquæ,	ʒiij.

M.

Sig. One drachm in water three times a day after meals.

—*Med. Bull.*

The taste of turpentine is said to be thoroughly disguised in the following combination:

℞

Oil of turpentine	2 fl. drs.
Glycerine	1 fl. oz.
Mucilage acacia	½ fl. oz.
Peppermint water, to make	8 fl. oz.

—*Pharm. Era.*

Constitutional Syphilis.

A mixture often ordered by Dr. Keyes is thus composed

℞

Potass. iodid.,	ʒij.
Ammonii carbonatis,	ʒss.
Tr. cinchonæ comp.,	ʒiv.
Syr. aurantii cort,	ʒjss.
Glycerinae,	ʒj.

M.

Sig. A teaspoonful, well diluted, after each meal.

—*Ther. Gazette*

Protracted Croup.

Davis.

℞

Potassium iodide	2½ drachms.
Tincture bloodroot	4 drachms.
Syrup squills compound	1½ ounces.
Camphorated tinct. opium	2 ounces.

Teaspoonful every four hours.

—*Phar. Era*

Habitual Abortion.

In habitual abortion, not due to syphilis, Negri recommends

℞ Mist. asafetida,..... ℥viij.

Sig. A tablespoonful several times daily.

—*Lancet-Clinic.*

Collodion for Gouty Joints.

℞ Morphinae acetatis..... gr. xx.
Acidi salicylici..... ʒij.
Ætheris.
Colodii flexilis,..... aa ℥vij.
Misce.

To be applied to the painful joint.

—*Ex.*

Secondary Syphilis.

In the secondary stage Ohmann-Dumesnil prescribes the following;

℞ Hydrargi bichloridi,..... gr. iv.
Ammonii muriat.,..... gr. viij.
Tinct. Cinchon. co.,..... ʒj.
Syr. sarsaparillæ co.,
Aquæ destillat.,..... aa ʒjss.

M.
Sig. Teaspoonful in water after each meal.

Uremic Vomiting.

Lecorche and Talamon use the following:

℞ Acid lactic..... mxv-xxx.
Syrup menthae pip..... ʒj.
Aquae destillat..... ʒiij.

M.

—*N. E. Med. Mo.*

Hiccough.

(In obstinate cases with extreme debibity).

℞ Hydrargyri chloridi mitis..... gr. j
Sacchari lactis..... ʒss.
Misce et. fiant chartulae No..... xij.

Sig. Take one powder every hour.

—*Dr. Gerhard.*

Chancroids.

For the cure of chancroids Dr. Adinell Hewson, of Philadelphia, advises this treatment: The penis to be washed with hot water and the following lotion applied locally:

℞ Hydrarg. chloridi mitis..... 2 drachms.
Liquor calcis..... 3 ounces.
Listerine..... 1 ounce.

Mix.

A Valuable Counter-Irritant in Diseases of the Chest.

℞ Aceti cantharides..... ʒij.
Spiritum camphorae..... ad ʒi.
Misce et fiat linimentum.

Apply to the chest at bedtime until redness is produced.

—*Practitioner.*

General Nervousness and Depression of Spirits.

The following is given by Dr. Emmet:

℞ Strychniae sulph..... gr. j
Quiniae sulph..... ʒss
Ferri pyrophosphat..... ʒij.
Spiriti chloroformi..... ʒiij.
Glycerinae..... qs. ʒiv.

M. Sig. One teaspoonful in wine glass of water four times a day.

Hooping Cough.

℞ Acidi nitrici diluti..... ʒxij.
Syrupi simplicis..... ʒiii ss.
Aquae destillatae..... ʒi.

M. Sig. Take a teaspoonful every three hours.

—*Dr. Hazard.*

For Disguising the Taste of Cod-liver Oil.

℞ Oleum gaultheriae
Oleum sassafras..... aa 4 parts.
Oleum aurantii flores..... 2 parts.

S. One drop to the ounce of oil.

—*Gazetta degli Aspitali.*

Scabies and Head Lice.

Prof. Tilbury Fox uses the following lotion:

℞ Hydrargyri chloridi corrosivi. gr. iv.
Alcoholis..... ʒvi.
Ammonii chloridi..... ʒss.
Aquae Rosae, q. s. ad..... ʒvj.

M. Sig. Apply once daily

Asthma.

℞ Potasiii iodidi..... ʒiij.
Extracti belladonnae fluidi..... ʒi.
Extracti lobeliae fluidi..... ʒij.
Extracti grindeliae fluidi..... ʒss.
Glycerinae.....
Aquae destillatae ãã..... ʒjss.

M. Sig. Take a tablespoonful every two, three, or four hours, as necessary.

—*Bartholow.*

Or this:

℞ Chloral hydratis..... ʒvj.
Syrupi tolutani..... ʒi.
Aquae fœniculi q. s. ad..... ʒij

M. Sig. Dose, a teaspoonful every half hour or hour, until relieved.

—*Weir Mitchell.*

Anæmia and Chlorosis.

Prof. Goodell recommends:

℞ Tincturae ferri chloridi..... ʒij ss.
Acidi phosphorici diluti..... ʒiij ss
Syrupi acidi citratis q. s. ad..... ʒiv.

M. Sig. Take a dessertspoonful in water three times a day.

Scarlet Fever.

Dr. Wilson has employed chloral throughout the entire attack with asserted good results in the following manner: so soon as the patient is suspected or known to be developing scarlatina, a laxative dose of calomel, proportionate to the age and general condition is administered. Shortly thereafter chloral is given in moderate doses, at intervals of two or three hours, or longer, throughout the attack. The dose varies with the age of the child; the frequency of its administration depends largely upon its effect. To infants of two or three years a dose of from 1 to 2 grains may be given, the dosage being gradually increased with older children; that for adolescents reaching 5 grains. The tranquillizing and sleep-producing effects of the drug are, in most instances, promptly realized, the patient falling into a condition of quietude instead of the restlessness and jactitation which are so distressing in the well-developed disease.—*Hare's Therapeutics.*

PERISCOPE.

MEDICINE.

Tetany in Children.

Loos has written an article on tetany in children, in which he gives laryngismus stridulus as the most important symptom in the disease; the following are in conclusion:

(1) Tetany is a frequent disease of early childhood, and has well-recognized symptoms.

(2) It begins relatively seldom with spontaneous tonic contractures of the extremities.

(3) Its presence is proven by the diagnostic sign of spasm of the larynx.

(4) It is not definitely settled whether spasm of the larynx alone is sufficient to establish a diagnosis of tetany.

(5) The symptoms of the disease are explained by the unusual excitability of the peripheral nerves and muscles.

(6) The excitability is caused by different irritants.

(7) The reason for this excitability is not known.

(8) The disease is more frequent in certain months of the year (spring).

(9) Tetany has no causal relation to rachitis.

SURGERY.

The Symptoms of Hip Joint Diseases.

Dr. A. M. Phelps concludes that the important early symptoms of hip joint diseases occur in the following order:

1. Limiting of motion. 2. Deformity with apparent lengthening or real shortening. 3. Limp. 4. Atrophy (in bone disease). 5. Pain in knee (with absence of knee joint disease). 6. Pain on joint pressure. 7. Night cries in absence of other joint disease. 8. Flattening of buttock and change in gluteal fold. 9. Heat. 10. Swelling.—*New Eng. Med. Mon.*

The Nasal Douche.

Dr. L. A. Dessar says the following rules should be observed in the use of all nasal douches:

1. The handkerchief should not be used for at least ten minutes after douching, inasmuch as in blowing the nose, any fluid remaining in the nasal passages may by a Valsalve action be forced into the Eustachian tube.

2. After douching it is advisable for the patient to remain indoors, so as to avoid exposure to the cold air.

3. During the proceeding the patient should not be disturbed or excited, as this may give rise to an involuntary attack of sneezing, coughing, or swallowing, and thus render it possible for fluids to enter the middle ear.

4. Before beginning the douching a careful examination should be made to see whether both nostrils are free. If one of them is found to be obstructed the douche should be used on the affected side.

5. Plain water should never be employed for douching, as it loosens the nasal epithelium. The addition of a small amount of sodium chloride prevents this action.

6. Concentrated solutions should never be used as a douche.

7. It is not advisabled to douche the nose more than three times daily. As a rule, its application morning and evening is sufficient.

8. The quantity of fluid introduced should not exceed ten ounces, the average amount varying from five to ten ounces; *i. e.*, from one to two douche cupfuls for each nostril.

9. The fluid should always be luke-warm. —*Inter. Jour. Surg.*

A Statistical Study of the Mortality from Anæsthetics.

Gurlt has continued for another year his collection of statistics for the purpose of studying the relative danger in the use of chloroform, ether, and other anæsthetics, and reported at the last meeting of the German Society of Surgeons on a material of 109,230 cases. There were 94,123 cases of anæsthesia by chloroform, 8,431 by ether, 2,891 by a mixture containing both, and a few with other drugs. With chloroform there was one death in every 2,614 cases, and with ether one in 7,431, while there was also one death in the few with the mixture.—*Centra fur chir.*

NEWS AND MISCELLANY.

The American Association of Obstetricians and Gynecologists will hold its sixth annual meeting at the Russell House, Detroit, Mich., on Thursday, Friday and Saturday, June 1st, 2nd and 3rd, 1893, under the presidency of Dr. Lewis S. McMurtry, of Louisville.

The following is the preliminary programme as far as titles are announced:

1. The President's Address, "The Present Position of Pelvic Surgery," by Dr. L. S. McMurtry, Louisville.
2. "Abdominal Fixation," by Dr. Florian Krug, New York.
3. "Endoscopic Tubes for Direct Examination of the Interior of the Uterus and Bladder," by Dr. Robert T. Morris, New York.
4. "Placenta Previa," by Dr. William H. Wenning, Cincinnati.
5. "What are the Indications for Abdominal Section in Intra-Pelvic Hemorrhage?" by Dr. M. Rosenwasser, Cleveland.
6. "Treatment of Metritis," by Dr. E. Pietranera, Cordova, A. R.
7. "A Plea for better Surgery in the Closure of the Abdominal Incision," by Dr. H. W. Longyear, Detroit.

8. "Remarks on the Treatment after Abdominal Sections," by Dr. C. C. Frederick, Buffalo.
9. "The Management of the Abdominal Incision," by Dr. Charles A. L. Reed, Cincinnati.
10. "Dilatation of the Cervix for Dysmenorrhea," by Dr. E. M. Pond, Rutland.
11. "Intra-Uterine Pregnancy; With Report of Cases," by Dr. George S. Peck, Youngstown.
12. "A Contribution to the Study of Ectopic Gestation," by Dr. E. Arnold Praeger, Nanaimo.
13. "A Few Practical Notes on the Establishment of Anastomosis between the Gall-Bladder and Intestine for Obstruction of the Common Duct with the Relation of a Case of Obstruction of the Common Duct by Small growth," by Dr. James F. W. Ross, Toronto.
14. "Vaginal Hysterectomy for Malignant Disease," by Dr. Rufus B. Hall, Cincinnati.
15. "The Care of Pregnant Women," by Dr. John Milton Duff, Pittsburg.
16. "A Contribution to the Pathology of Surgical Disease of the Gall-Bladder," by Dr. Walter P. Manton, Detroit.
17. "The Legal Questions in Gynecological Operations on the Insane,,' by Dr. Walter P. Manton, Detroit.
18. "Pelvic Abscess," by Dr. I. S. Stone, Washington.
19. "Central Rupture of the Perineum; Its Causation and Prevention," by Dr. John C. Sexton, Rushville.
20. "A Case of Myomectomy with Extra-Peritoneal Treatment of the Pedicle, followed by Pregnancy and Complicated by Hemorrhages through the Abdominal Cicatrix," by Dr. X. O. Werder, Pittsburg.
21. "Anatomy and Surgical Importance of the Peri-Renal Cellulo-Adipose Tissue," by Dr. L. H. Dunning, Indianopolis.
22. "Report of Cases from Practice with Remarks on the Same'" by Dr. A. Vander Veer, Albany.
23. "Further Observation on the Relation of Pelvic Disease and Psychical Disturbances in Women," by Dr. George H. Rohe, Catonsville.

A cordial invitation is extended to the members of the medical profession interested in the work of the Association to attend its several sessions.

By order of the Executive Council.

WILLIAM WARREN POTTER, Secretary.

ARMY AND NAVY.

U. S. ARMY, FROM APRIL 16, 1893, TO APRIL 22, 1893.

Major Henry M. Cronkhite, Surgeon U. S. Army, will proceed to Fort Wadsworth, N. Y. H. and report to the post commander for temporary duty.

U. S. ARMY, FROM APRIL 23, 1893, TO APRIL 29, 1893.

The leave of absence granted Lieutenant Colonel Charles C. Byrne, Deputy Surgeon General, U. S. Army, is hereby extended one month.

Captain Wm. O. Owen, Jr., assistant surgeon, is relieved from duty at Jefferson Barracks, Mo. and ordered to Fort Bayard, N.M. for duty.

Captain Edward T. Comegys, assistant surgeon, is relieved from duty at Fort Bayard, N.M., and ordered to Fort Wadsworth, N. Y. for duty.

Captain A. S. Polhemus, assistant surgeon, is relieved from duty at Fort Monroe, Va. and ordered to report at Fort Douglas, Utah, for duty.

Captain Wm. P. Kendall, assistant surgeon, is relieved from duty at Fort Douglas, Utah, and ordered to Willet's Point, N. Y. for duty.

Captain Wm. F. Carter, assistant surgeon, is relieved from duty at Willets Point, N. Y. and ordered to Fort Sill, O. Ty. for duty.

Captain B. D. Taylor, assistant surgeon, is relieved from duty at Fort Sill, O. Ty. and ordered to Fort Bliss, Texas.

Captain Wm. B. Banister, assistant surgeon, is relieved from duty at Washington Barracks, D. C. and ordered to Fort McIntosh, Texas, for duty.

Captain George McCreery, assistant surgeon, is relieved from duty and ordered to Fort Sidney, Nebraska, for duty.

Captain Louis S. Tesson, assistant surgeon, is relieved from duty at Fort Sidney, Nebraska and ordered to Jefferson Barracks, Mo. for duty.

Leave of absence for one month on surgeon's certificate of disability, with permission to leave the limits of the department to take effect when Assistant Surgeon Ware shall have returned to Fort Supply, I. T. is granted Captain Marlborough C. Wyeth, Assistant Surgeon, U. S. A.

Leave of absence for twenty days, to take effect after May 1st, 1893, is hereby granted to Major Ezra Woodruff, Surgeon U. S. Army.

First Lieut. Ogden Rafferty, Assistant Surgeon, to be Assistant Surgeon, with the rank of Captain, from March 26, 1893, after five years' service, in conformity with the act of June 23, 1874.

First Lieut. Francis A. Winter, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Wingate, N. M. and will report in person to the senior commissioner of the International Boundary Survey Commission at Yuma, A. T. for duty, relieving First Lieut. Harlan E. McVay, Asst. Surgeon.

First Lieut. McVay on being relieved by First Lieut. Winter, will report in person to the commanding officer San Carlos, A. T. for duty at that station relieving Captain Paul Shillock, Assistant Surgeon.

Captain Shillock, on being relieved, by First Lieut. McVay, will report in person to the commanding officer, Fort Wingate, N. M. for duty at that post.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.
(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

Pil. Lady Webster.
(WM. R WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.
(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion; and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.
(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

Mellin's Food
For Infants and Invalids.

A SOLUBLE DRY EXTRACT of Barley Malt and Wheat, for addition to Fresh Cow's Milk.

Prepared upon the principles advanced by the eminent chemist, Baron Justus von Liebig.

EXPERIENCE — the supreme test — has absolutely proven that the best solution of the problem of infant feeding was made by LIEBIG, and that MELLIN'S FOOD prepared with milk is the nearest approximation to, and is the BEST SUBSTITUTE for, Mother's Milk which has ever been devised.

GYNECOLOGY AND THE GENERAL PRACTITIONER.*

JOSEPH PRICE, M. D., Preston Retreat.

While, as physicians and surgeons, we cannot escape a painful and mortifying sense of many failures, it is gratifying, encouraging, and assuring to have afforded us by the most casual retrospect so many evidences of progress. It is a matter of cheerful congratulation that we live in a period of intense professional energy, activity and research. The advances in medical and surgical science in the past quarter of a century have greatly exceeded those of any corresponding period of the past.

When we come to look for the sources of our advances—of our better knowledge—we must credit largely the use of our greatly improved clinical opportunities, the more generally recognized primary importance of thorough preparation for the work we propose and attempt to do, and the elevation of the standard of medical and surgical education. And there is more and better where all we have came from. So far as books have served us as educational manuals, have been clear, logical, definite and specific in aim, they have served us a valuable purpose. They are too many, and many of them are too crowded with errors and exploded theories, are too confusing and misguiding to entitle them to a place in the alcoves of our private or public libraries. Many of them work mischief, they "are only commentary and elucidation, echoes and weakners of the few great voices of time." Since our duties are exacting, our time all too short to waste over the productions of the pens of the mediocrites, we should with keenest scrutiny and choice, select from the most select of the masters, those whose genius have built up our science, and from those of our own period who keep abreast with every modern advance; those who would rather do than write, who simply give the lessons their experience affirm. The diagnosis of the books in many instances does not fit our case. Further our education should not be limited to our heads. Napoleon said, "my hand is immediately connected with my head." The fingers and the eyes are the instruments of instruments—in them there must be cultivation and adaptation to our surgical work; there must be no mistake or wavering of courage in their second to our surgical intelligence. Our mechanical aids are many and valuable—but for success there must be sound surgical sense at the wheels.

As close, ready and trained allies of our knowledge of anatomical and pathological conditions, of the importance, functions and relations of structures, there must be apt and dexterious fingers—fingers trained to ease and certainty in their work—sufficiently sensative to distinguish the difference between the edge of a razor and that of a meat axe, and acute eyes that draw *hair lines*. The mental map of the work to be done must have in its lines the finnesse of an artistic touch. All this comes from many experiences—of long

* Read before the Lancaster Co. Penna., Medical Society, May 3rd, 1893.

and patient training. We do not get this discipline from the books, nor is it attained by little study, limited clinical research or few experiences. It is not the product of months but of years—not of two years or four years—but of many.

There is a point in the following little anecdote: Hyde, Earl of Rochester, asked Lord Kæper Guilford, "Do you not think I could understand any business in England in a month?" "Yes, my Lord," replied the other, "but I think you would understand it better in two months."

Medical and surgical sense is obtained, as other kind of sense is obtained, by work.

In matter of work there is no class of men in any department of human affairs whose time and energies are more severely taxed than those of the active practitioner of medicine. Per-virtue his calling he is at the bidding of the community in which he pursues his profession. Superiority of skill and knowledge only augments his labors, adds to his duties and responsibilities. He is the first appealed to, the first called in cases of disease or accident. These facts urge the importance of his thorough equipment. There are no resources in the science of medicine and surgery to which the needs of his field do not appeal. He is summoned to deal with all forms of disease and accident. He must know something of many subjects; though it has been said by an eminent American scholar—that, "he is a learned man who understands one subject, and he is a very learned man who understands two subjects." The general practitioner is the all-round consultant, and in the very nature of things will continue to be. His school, the bedside, is the greatest and best of all. He determines the therapeutical and clinical value of remedies, knows and adhers to those which have given the best results. The experimentor or so-called scientist tells us just how our remedies act—what organs they affect; he tells it by putting a hot iron in a cat's ear and making it spin around on the other ear; how the heat centers are influenced by placing a clinical thermometer in a goat's rectum, or a pigeon or rabbit in a hot oven, followed by a cold bath.

It is in the gynecological field that the general practitioner encounters many grave difficulties, and has demonstrated the urgent need of his fitting himself for the early recognition of those troubles requiring surgical interference—those in the dealing with which there is need for the prompt service of the gynecological specialist. I have no desire to give to gynecology pre-eminence over other specialties, but would press upon your attention only those honest claims sustained by the happy results of modern experience, those for which many suffering women have need to be grateful.

Gynecology has taken its position, and it is not a secondary one in medicine, using the term medicine in a generic sense. The position taken and maintained by this branch of our healing and life saving service has not been attained or maintained without the encountering and overcoming of many bitter antagonisms. The vantage ground gained is such that it now holds, and always will hold its own; its importance as a specialty grows in both professional and popular recognition, and this recognition will continue to grow as we break away from antiquated and exploded errors.

Our gynecological procedures have passed without the field of mere adventure and experiment into one with many certainties. The general practitioner has no reason to complain of gynecological specialism—there can be no divergence or severance of interests, they will continue mutual in the study and treatment of the diseases of women; they serve each other as co-workers in saving the lives and mitigating the suffering of women.

There is a growing tendency to specialize into gynecological surgeons and obstetric physicians. There is a danger of this tendency carrying us too far. While it may not be essential or possible to be specialists in both branches, we cannot safely sever their interests. In elevating the importance of one we do not discount the importance of the other. Obstetrics has advanced to a point of an accurate science, for the educated and experienced obstetrician it has its certainties, its procedures of undisputed wisdom. The gynecologist cannot be the best as such—reach the best in uniform results—without a knowledge of obstetrical art and science.

The distinguished French gynecologist, M. Auvord, with aptness says, "obstetrics is practically to gynecology what physi-

ology is to medicine, they are closely connected and one cannot progress without the other."

The successful specialist must have several years of active general practice. It is in it he gains his first and best lessons in practical obstetrics and in the diseases peculiar to women; it is in this general practice he first encounters, the one among many gynecological difficulties, that of rational diagnosis. The accurate diagnosis of obscure and complicated conditions is in many cases very difficult, and is the source of great mental perplexity and anxiety; in fact in many cases it is impossible without surgery—even by the specialists. Unfortunately all of us have been taught the use of a variety of instruments we could wisely dispense with, for instance the sound, tubular and bivalve specula; while they are not needed in the hands of the trained and experienced, in the hands of the unskilled and inexperienced they are dangerous and should not be found. Careful training in diagnosis with the fingers, first as to normal conditions; second deviations from the normal, objective symptoms—these are easily practiced methods. Careful examination by exclusion will rarely lead us into error. Sometimes it is difficult for us to say precisely what the trouble is, but we can commonly reduce it to one of two things. For instance an abscess of the ovary may simulate in subjective and objective signs a small suppurating dermoid—it is not important which it is, there is but one treatment for the two troubles.

Again the uterus is retroflexed and adherent with an occluded and distended tube on one side acutely inflamed and strongly adherent, there may be a history of delayed or absent period with agonizing pain. You cannot dismiss tubal pregnancy nor can you exclude suppurating tube and ovary, notwithstanding symptoms strongly favor the latter. Here again the treatment is precisely the same for a serious mischief that must be removed.

Again pelvic growths and inflammatory troubles are commonly missed. You may have an extra-uterine pregnancy on the left side and a dropsical tube on the right side, or a small cystoma with occluded tube on the right side, a pus tube and an ovarian abscess on the left, and omentum and intestine strongly adherent; above from sigmoid to vermiform appendix.

These troubles are so common and so mixed in nature that it is perfect folly to boast about refinement in diagnosis. If you claim a pus tube on the left side you must also recognize the left ovarian abscess if it exists or double pus tubes with an ovarian abscess on the right—or keep quiet and simply say you have diseased tubes and ovaries on one or both sides with adhesions.

We frequently find slight or extensive lacerations of cervix, cervix eroded, lips everted and studded with small cysts. In many of these cases the uterus is either retroverted or retroflexed, the patient should be put to bed, the cervix freely punctured and the uterus placed in its normal position. If the laceration extends to the vaginal vault it should be well closed. If there is relaxation of the vaginal outlet with cysto and recto vaginocele the pelvic floor should be restored by Emmet's inside perineal operation. Injuries and diseases of the urethra should be studded and treated with care.

Complications antedating operation should always be released, or they remain sources of post-operative danger and suffering.

The simple removal of a tumor without freeing an adherent omentum of bowel is imperfect surgery. It is the incomplete, imperfect and abandoned work from which so many women are suffering. Incomplete work is also a cause of early deaths. To illustrate, you remove a huge pus tube or ovarian abscess, universally adherent, and you fail to recognize a coil of adherent ileum. She dies the third or fourth day with bowel obstruction. The fact that an operation has not killed is not the best evidence of successful surgery—the sequelæ must be considered, is the determining factor.

There should be the diagnostic ability to recognize the precise nature of the trouble at its very inception, before there are alarming symptoms of advanced disease. In early parturition, all accidents incident to it should be carefully and completely repaired thus favoring speedy and satisfactory convalescence and prevent many serious post-puerperal complications.

Not a few men yet discuss the question of the removal of the appendages with something of bitterness and more of ignor-

ance. Undoubtedly a great number of operations are done for the fee, or they are done because the operator has nothing else to do. He has chosen his specialty and must stick to it. Unfortunately these men carry the matter of removal too far. They sometimes counsel the removal of the appendages for vague nervous symptoms, without a subjective symptom to warrant this counsel. Again they will protest vehemently against the removal of disorganized structures, disorganized tubes and ovaries, wholly worthless and destroying the patient's life. This is either ignorance or it is something worse than ignorance. Some of them carry into the work a professional conscience as coarse in fibre as that of an old rag carpet. The rights and duties of maternity are not to be ignored. Where there is possible chance the cherished right of motherhood should be sacredly guarded. Again we have patients who demand a certain operation, ignoring the possibility of matrimony, this demand should not be yielded to.

Women should not be permitted to go on suffering where symptomatic treatment has been tried and failed—there should be resort to radical measures. The physician should have precise knowledge of the nature of the trouble and should not go on blindly treating something he imagins to exist. Whatever the treatment, whether medical or surgical, all possible issues should be anticipated.

Where the treatment must be surgical the patient and family should be frankly and fully informed of the nature of the trouble, and as nearly as can be anticipated the probable or possible results. This should be done in such a manner as to avoid unnecessary alarm.

I cannot say anything better in this connection, certainly nothing with the weight of better authority, than that said in the report of his first case of successful peritoneal section by one you all hold in close and honored memory, John L. Atlee. After describing the conditions of his patient, he says: "It was now my duty to state to her with candour and frankness, her real situation. If left to itself, her disease must prove inevitably, and from her recent symptoms perhaps rapidly fatal. The tumor on the right side was obviously a compound ovarian tumor. Were it like that on the left side—apparently a simple cyst—the accidental or designed rupture of it, were there but one, might terminate favorably, but even of this event there was only a remote possibility, and but few favorable cases are recorded. The right tumor, however, was not of this character, and but one remedy, that of extirpation, could prove effectual. I frankly informed her of the magnitude, and of all the dangers of the operation; concealing nothing as to its immediate or remote consequences; to her immediate friends and relatives, who hold a highly respectable station in society, a similar statement was made; and after ample time for deliberation and consultation with them, she determined upon having it performed.

It was not until my heroic patient made known to me this decision, that I felt in all its aspects the great responsibility resting upon me. I felt it my professional duty to inform her that an operation could be performed for relief—but it was one which met with but little countenance from the profession."

If such good conscience, great candour and courage as that displayed by Atlee, characterized the profession more generally, with less charlatanism, we would have fewer malicious legal prosecutions, less blackmailing, less pretext for many of those professional annoyances to which we are exposed, fewer refusals to pay for honest professional service.

We will pass in brief review some of the many difficulties which the general practitioner encounters in dealing with gynecological cases—from a number of these difficulties the gynecological specialist is not free. They have no special order of importance, they are all embarrassments to good and successful work.

There is nothing more sad or melancholy in our experiences than the repeated instances in which a commercial value is placed upon a human life. I will give in illustration a recent instance in my own experience.

A creature (I avoid the names man or gentleman to avoid misnomer) from a border state brought his wife to me. She was suffering from a tumor. She was emaciated, her face was all lined with the traces of her suffering, and without surgical interference and relief there was before her a life of misery, of incapacity for social or domestic duties. I advised im-

mediate operation, while conditions favored rapid and complete recovery.

The husband inquired what my fee would be. I fixed it very low, little more than covering the nursing and actual hospital expenses. He turned to his wife and said: "Mary, you can keep your tumor." I have had many kindred experiences in my practice and, doubtless, many of you have had them in yours. Where our professional duty is faithfully and conscientiously discharged we earn all we get. Where there is ability to pay it should be liberal. There is labor, responsibility, sacrifice, untold anxiety in our work,—there is no class or body of men on earth who do more charity, practice a broader and more practical philanthropy than our physicians and surgeons.

Again while emulation of the best is creditable to us, the envy and jealousies that sometimes characterize the conduct of members of our profession works far-reaching mischief. Where such motives control the influence for evil is not a feeble one.

Doctor A. and B. are called to a case, they recognize serious trouble and counsel well-directed and safe treatment—but heroic. C. and D. oppose their suggested treatment and are favored by the family, that the surgical interference suggested by A. and B. may be avoided. Often C. and D. know better or should know better—but if they give the same opinion the patient will go to A. and B.

She is left to suffer on; nothing new is done; the old treatment is continued. At last the patient in her desperation and despair demands that something be done—life has become intolerable. *It is too late.* Primarily the chances in favor of relief and prolonging life were ninety-nine in one hundred. Now they are reversed, in one hundred the chance is *one. To that one chance she is entitled.* No matter if in giving that one chance there should be one added to the statistics of the mortality of the surgeon—and there should be men mean enough to advertise it. Such experiences are exceedingly common. These conflicts of opinion, more frequently the outcome of envy or jealousy than of intelligent, sober and deliberate judgment, arise in relation to every disease, in relation to ovarian tumors, and the various diseases of the uterus and its appendages, which call for absolute operative interference; the class of cases which medicine can not benefit, the knife the *only* remedy.

Only very lately I saw in consultation two lovely women, women typical in every way of our best American womanhood, both wives of physicians, both had been permitted to suffer for a long period through the disagreeing, the timidity and ignorance of physicians; they received a great variety of treatment for a great variety of troubles—they lingered along in horrible suffering—relieved only by death. The post mortems revealed that tubes and ovaries, bladder, bowel, in fact the whole pelvic contents were involved in a basin of pus. These experiences have been repeated in several cases I have seen in the past few months, cases in which all the conditions were such that I urged operation. Adverse counsel prevailed, much valuable time lost, all the more dangerous symptoms becoming greatly aggravated, the surgery rendered more difficult and perilous. Two of these cases are now in my private hospital, pitiable wrecks, alarmingly emaciated, feeble and exhausted. Operation in these cases was advised more than five months since, but family physicians and their consultants held out the hopes of palliative treatment and exaggerated the sufferings and risks of surgical treatment. I urged these patients to return to their physicians, present my compliments, and insist that they take care of them, that their deplorable condition was due to their counsel and treatment, and that by the delay, for which they were responsible, the complications and risks of operation had been greatly increased and recovery far removed from reasonable certainty. The honesty and methods of such men would give them high rank in our politics.

There is no question that confronts the general practitioner with so much perplexity in it as that of deciding the propriety or necessity of an operation. This fact presses the importance of familiarizing himself with the work and methods of abdominal surgeons. He should have the ability to diagnose conditions requiring surgery for their removal. Where doubt exists an experienced specialist should be called in. Unfortunately in so many cases of abdominal and pelvic trouble the conditions become grave before the specialist is consulted; they go to him only after symptoms become desperate. As to

who should do abdominal surgery, the answer should be emphatic, only those who have had special training, years of clinical study and practical experience, those who by predilection have given the subject long and masterly study. There is too much reckless dealing with the peritoneal cavity. Many disasters are due to overzeal, to surgical ambition, to essaying into fields for which they have received no careful preliminary education, none of the training which comes only of experience, long, patient and hard clinical research and observation. Very often the failure of the general practitioner in the matter of diagnosis is not so much from lack of knowledge as because gynecological examination is objected to by the patients. This fact prevails more strongly in the country and country town than in the city. In not a few cases men's practice has been driven from them by the accusation that they were addicted to gynecological examinations. The more close social intimacy of the country physician with his patients than as a rule are those of the city, may somewhat explain this over-sensitiveness to examination. And the more intimate association of women among themselves has much to do with it. So profound is our reverence for feminine modesty that we will only refer to its practice under such circumstances as a mistaken modesty, often leading to very painful and alarming results. Neither do men like to examine women with whom they are on terms of social intimacy. Much will be accomplished when an unreasoning aversion to vaginal examinations is broken down. There should be no fuss about it. Where the necessity for vaginal examination is clearly indicated—it should be proceeded with not as something extraordinary, but as a matter of refined delicacy, yet of professional duty. The physician making such examinations should be one of highest honor, of clean life, clean conscience and clean hands. There should be reasonable certainty as to its necessity, and it should be conducted with a propriety of manner dictated by a high sense of appreciation of feminine delicacy. The woman finds pain enough in the consciousness that her trouble is such as to require such an examination.

In many forms of pelvic trouble the importance of careful and repeated examination cannot be too strongly urged. Again the careful preparation of patients is of vital importance.

The examination of a patient at her home should be anticipated by a laxative and her bladder should also be emptied just before examination. The examination should not be upon a low bed. The patient should be placed on a table or pulled well to the edge of a firm bed. The position of the uterus, size, consistency, outline and relation to surrounding parts should be carefully investigated. And it should be remembered that you cannot isolate conditions, there is always a relation to other conditions,—all displacements involve altered relations.

If an ocular examination is necessary, or local treatment indicated, the side position and Sim's speculum should always be used. Local treatment and tinkering of all kinds, surgical and intra-uterine, stretching, rupturing asunder the cervix, sewing it up, incising it fore and aft or latterly have been and are still practised with too great freedom. The loose and indiscriminate practice of many of these procedures has driven many women to heroic procedures to save their lives. Patients should not be permitted to go on suffering indefinitely where symptomatic treatment has been tried and failed—there should be resort to radical measures, and in all cases possible issues should be anticipated. The very ease of some minor operations tempts men without any special training in surgery to their reckless and inconsiderate performance, without thought of the possibilities of consequent mischief.

I removed disorganized tubes and ovaries from a woman who had been confined to her bed for six years, had been treated in four different states by thirty-four different doctors. She received every treatment known to the books, ancient and modern. She was a hopeless invalid, in fact such treatment and so much of it would invalid the toughest human specimen. When we consider what has been accomplished in abdominal surgery we are impresssd by a sense of the yet greater possibilities in the keeping of a near future. Our victories of to-day presage yet greater victories for our to-morrow. When we consider the long stretch of years between Ephraim McDowell of Virginia and Lawson Tait of Birmingham, England, and your own

Atlees we can appreciate the slow growth of much of the triumphant surgery of our period. Typical of all other progresses has been that of surgery. McDowell, in the first ovariotomy ever performed (December 1809) had without the door a sceptical, doubting, angry, vengeful crowd, awaiting the result of "butchering the woman," as they termed it. Mr. Tait in devising and perfecting the procedure had the courage to battle his own way through the stubborn lines of doubting, envious and jealous men until his methods and procedures became the accepted and practiced procedures in our abdominal surgery.

It is the work and voice of such noble, courageous and unselfish men as I have here named that make the history of the profession interesting and profitable reading. It is such men who, with no mean envies smouldering in their blood, look upon individual success as part of the common honor and glory of the profession and lend a willing hand and voice in promoting that fellowship which strengthens our efforts in battling with all forms of disease. Our debt to such men as our teachers, is beyond our reckoning. Largely all we know is of their teaching. None of us have grounds for boasting of our knowingness, when we contrast the little we know with the vastness of what we don't know. We have a great pride in our profession, find a great gladness in each new triumph, honor the individual victors for the new steps they contribute to our easier and more successful climbing.

COMMUNICATIONS.

METATARSALGIA (MORTON'S PAINFUL AFFECTION OF THE FOOT), WITH AN ACCOUNT OF SIX CASES CURED BY OPERATION.*

THOMAS S. K. MORTON, M. D.†

The affection that has come to be best known as "Morton's Painful Affection of the Foot," or "Morton's Toe," was first described and a method of certain cure presented by Dr. Thomas G. Morton, of Philadelphia, in 1876, under title of "A Peculiar Painful Affection of the Fourth Metatarso-phalangeal Articulation."[1] In subsequent publications[2] he has confirmed his views relative to cause and treatment, and reported large numbers of cases.

The disease under consideration may be described as a painful affection of the plantar digital nerves, directly caused by pressure upon or pinching of them by certain portions of the metatarso-phalangeal articulations—especially the fourth.

The reason for the fourth toe being the almost invariable seat of origin of the train of painful and neurotic symptoms to be described is ascribed to anatomical causes by Morton in the following language:

"The occurrence of neuralgia may be understood by a referenee to the anatomy of the parts. The metatarso-phalangeal joints of the first, second, and third toes are found on almost a direct line with each other, while the head of the fourth metatarsal is from one-eighth to one-fourth of an inch behind the head of the third, and the head of the fifth is from three-eighths to half an inch behind the head of the fourth; the joint of the third, therefore, is slightly in advance of the joint of the fourth, and the joint of the fifth is considerably behind the joint of the fourth.

"The fifth metatarsal joint is so much posterior to the fourth that the base of first phalanx of the little toe is brought on a line with the head and neck of the fourth metatarsal, the head of the fifth metatarsal being opposed to the neck of the fourth.

On account of the character of the peculiar tarsal articulation, there is very slight lateral motion in the first three

*Read before the Philadelphia Academy of Surgery, March 6. 1893,

†Professor of Surgery in the Philadelphia Polyclinic, etc.

1 *American Journal Medical Sciences*, January, 1876.

2 Surgery in the Pennsylvania Hospital, 1880, p. 107. *PhiladelphiaMedical Times*, October 2, 1886.

metatarsal bones. The fourth has greater mobility, the fifth still more than the fourth. Lateral pressure brings the head of the fifth metatarsal and the phalanx of the little toe into direct contact with the *head and neck of the fourth metatarsal*, and to some extent the extremity of the fifth metatarsal rolls above and under the fourth metatarsal.

"The mechanism of the affection now becomes apparent when we consider the nerve-supply of the parts. The branches of the external plantar nerve are fully distributed to the little toe and to the outer side of the fourth; there are also numerous branches of this nerve deeply lodged in between these toes, and they are liable not only to be unduly compressed, but pinched by a sudden twist of the anterior part of the foot. Any foot-movement which may suddenly displace the toes, when confined in a shoe, may induce an attack of this neuralgia. In some cases no abnormality or other specific cause for the disease can be detected."

This explanation undoubtedly will account for the great majority of cases, and perhaps all could be ascribed to pinching of the nerves between the metacarpo-phalangeal articulation. Yet there have been reported a few cases where the transverse metatarsal ligament has appeared to be lax or ruptured, thus permitting the metatarsal heads to descend upon the nerves. Auguste Poullosson, of Lyons, in 1889,[3] after reporting a typical case, says that "the cause of the affection is evidently a certain laxity of the transverse metatarsal ligament, which permits partial infraction of the arch formed by the heads of the five metatarsal bones, one of the middle ones, probably the third, becoming dislocated downward and compressing the nerves running along each side of it against the heads of the neighboring bones."

L. G. Guthrie,[4] in writing of metatarsal neuralgia, states his belief that "under the influence of prolonged standing or walking in tight boots, the ligaments of one or more joints, metatarso-phalangeal only, become strained, slight sublaxation takes place, the nerves are stretched and pressed upon by the partially dislocated bones, and the characteristic pain is produced."

In reference to the supposed dislocations above mentioned, Morton says:

"The dislocation referred to is not a true dislocation, but is simply a twist of the toe, and a violent spasmodic condition of the muscles of the toe incident to the intense pain, simulating a dislocation, which, when the toe is compressed laterally and in its rolling between the third and fifth, suddenly presses upon and pinches the underlying plantar-nerve branch."

Edward F. Grün,[5] himself a sufferer from the affection, believes that the pain results from descent of the tarsal arch, which is accompanied by lengthening of the foot and spreading to the outer side, so that "where the weight comes on the member the foot spreads inordinately; the boot is not constructed to allow for so much spreading, and a frightful cramping pain is the result, causing the patient to remove the boot without regard to place or circumstances—often the most inconvenient."

E. H. Bradford[6] states that the results of treatment in these cases, as well as the symptoms and localization of the point of severest pain, make him agree with Morton, in believing the affection to be originated by pinching of the metatarsal nerve, rather than to flattening of the tarsal arch, as suggested by Poullosson. In none of his thirteen cases was any degree of flat-foot present.

In a large number of cases seen by me, in addition to those herein reported, it has not been possible to demonstrate any laxity of the metatarsal ligaments, and, while in a few the pain was referred to other of the metatarso-phalangeal joints than the fourth, yet upon careful manipulation it was always found that the pain was reflected from the fourth to the other joints. It must be conceded, of course, that laxity or rupture of the transverse ligament would predispose to injury of the nerves at the fourth joint by permitting greater motion of the overlapping bony points in that situation. However, while the exact etiology of the affection is of great scientific interest, clinically it is

of small account, as excision of the fourth metatarso-phalangeal articulation, as originally proposed by Morton, or amputation of the fourth toe, including the corresponding metatarsal head, invariably has secured an absolute and permanent cure. No dissections of the diseased regions have yet been possible, nor have the nerves been in any case excised so that microscopical examination could be made. I have carefully examined a number of the joints that have been removed for the cure of the affection, and in no instance have been able to prove any anomaly or disease.

Metatarsalgia is, in its lesser degrees, a very common disease. Almost every one has suffered more or less, at times, from neuralgic twinges radiating from the joint in question. These mild cases occasionally develop into the more severe forms. In them occasional attacks of pain are often followed by periods of complete immunity.

Morton made extended inquiries among retail shoe dealers and found "that this peculiar condition had not only been frequently recognized by them, but that it is also considered to be quite common. Almost every intelligent shoe retailer has seen a number of persons to whom this disease has been a source of a frequent suffering, and who believe their malady to be beyond relief by medical art; indeed, it would seem that in some of the most severe of the cases it has been found impossible to obtain the serious consideration by their medical attendents."

So recently as 1891 Bradford [7] has written:

"It is somewhat singular that an affection that is not infrequent in these days of thorough investigation of all ailments, should have attracted but little attention, either in the researches of surgeons or of neurologists. The cases are so usually classed among the ill-defined hysterical or nervous affections, and not thoroughly investigated; or they are deemed to be gouty, as in the minds of many practitioners, are frequently all affections of the toes."

The disease has not been observed before adolescence. Women are certainly more predisposed than are men, and its occurrence in the former sex I should judge to be almost twice as frequent as in the latter. One foot is almost usually involved, especially in those cases apparently taking origin from an injury. But very frequently one foot is affected to an almost unbearable degree, while its fellow is but slighly involved. Neither right nor left foot appears to be most liable to involvement unless one or the other is constantly subjected to a motion, as in running certain sewing machines, looms, lathes, etc., while the other is not employed. In this case, as in one of my own, the pain developed in the foot so employed. When both feet become simultaneously affected the cause will often be found in ill-fitting or tight shoes. Middle life is the period at which the disease is most apt to develop or to become severe. The aged are by no means exempt, although in them more purely gouty or neuralgic forms are prone to occur, and persons at any age, so predisposed, appear to be much more liable to the affection—idiopathic or traumatic—than are others.

The influence of heredity is very marked. I know of several families in which a number of persons, mainly confined to the female sex, are similarly affected. It is interesting to note that in these instances some cases have arisen from twists or sprains of the foot, and others apparently idiopathically.

The exciting or immediate cause of metatarsalgia is usually excessive or unusual exercise of the feet while confined in new, tight, or ill-fitting shoes, as in walking over rough surfaces (mountain-climbing), dancing, playing lawn tennis, etc., or in changing from a firm-soled shoe to one that permits great motion of the metatarsal arch. When the heads of the metatarsal bones are rigidly held in contact by a tight shoe it is reasonable to believe that a very slight twist or wrench of the foot would bring great pressure to bear upon the sensitive branches of the digital nerves distributed upon and about them, and, particularly in those predisposed thereto, bring about a neuralgic and even neuritic condition. This once set up, and the nerves having become sensitive, swollen, or inflamed, ever so slight repetitions of the pressure or bruising are capable of originating the most agonizing suffering. Later, continuous or frequently recurring attacks of this pain, or actual ascent of neuritis, commence reflex contractions and other neurotic complications,

7 Loc. cit.

perhaps of the gravest type, as witness in Case I. of my series, where the patient had become bed-ridden and severely neurasthenic.

So far as relates to symptomatology, I shall depend upon quoting a few more or less typical cases from the literature of the subject and upon the histories of my own operative cases, but may here mention that I regard the *imperative necessity of removing the shoe*, regardless of surroundings, when a paroxysm comes on, as a pathognomonic symptom of the disease. It may also be said that no evidence of the disease can usually be felt or seen, except that the parts are often of a bluish tint and cold, from venous stasis, and have a tendency to profuse perspiration.

Case I.—Miss I. F. S., aged thirty-one years, teacher, was brought to me by her physician, Dr. George L. Romine, of Lambertville, N. J., in June, 1892.

The following history was elicited: Family history excellent; she had always enjoyed the best of health and strength until the present trouble commenced. In July, 1890, she played lawn tennis for the greater portion of a day, coming down heavily on the balls of the feet many times, after which she walked a short distance to her home, and felt greatly fatigued. After resting two hours she attempted to walk and experienced a "queer sensation" along the outside of the left foot, a feeling "as if something had given way about half-way between the toes and heel."

"In the evening I walked down town, but could scarcely return, for it was so hard to make my foot go. I felt as if retarded in some mysterious way. By the time I reached home a line of pain extended from the place above-mentioned all the way to my hip. Thinking I had sprained my foot, I applied the usual remedies. The next morning my foot felt rested, but during a short walk on the street the pain in my foot and limb returned.

"By this time the foot began to swell, particularly along the outside, and in a few days had a reddish appearance. After a night's rest the swelling disappeared, and I was able to use my foot, with intervals of rest, in ordinary walking about the house. Each day it gave out after less use, so at the end of five days I called in our family physician, Dr. Romine, of Lambertville."

It was presumed that a ligament or tendon had been ruptured, and fixation by bandages resorted to. On August 7 these dressings were removed.

"The foot and limb were helpless, and the whole side of the foot felt so indescribably bad that it made me faint. A starched dressing was then put on the foot and limb to the knee. For four or five days following I held my foot on a chair, but after that, during part of the day, on a pillow on the floor. Toward evening I had almost unbearable tingling in the foot, but this passed away on retiring. I never could rest my foot on the outside from the time of the accident without having that unbearable feeling in the foot, and at times the line of pain in the limb.

"At the end of four weeks the Doctor told me to stand with my feet even. Never shall I forget what I suffered that day. The limb had shortened so that the heel was about two inches from the floor, and in trying to stretch it down the bottom of the foot pained and tingled dreadfully. I was completely exhausted and deathly sick.

"Crutches were then ordered, and I commenced my hard work of learning to walk.

"My foot was so bad on the side, and a line of dreadful pain extended from about two inches from the fourth toe along the side of the foot and to the knee. After a time the pain in the limb seemed better, but the whole side of the foot felt unspeakably bad. The uncomfortable sensation did not seem confined to any particular place on the side, as it did at first.

"The 1st of October the physician advised my going to school in order to overcome my nervousness, and take my mind from the foot. I wore a worsted slipper.

"The last of October the Doctor commenced the use of a battery every night—the interrupted current being used. The sponge was applied under and over the toes five minutes, five on each side of the heel, and five under the knee. The toes twitched a great deal, and I always dreaded when the sponge neared the fourth and fifth toes, for I felt the sting and jerk along the injured side, and it made me sick. I could bear only a light pressure there. When applied under the knee I felt the line of pain down the outside of the limb, and often the toes would jump. When the current passed down the inside of the limb it felt agreeable.

"My foot always felt badly on removing the shoe at night, and the limb above was very much swollen and glossy in appearance.

"The last of July, 1891, I took a short walk, without support, along the piazza. That night my foot pained up to the knee, and I was unable to touch it to the floor for more than a week. I was careful to take only a few steps at a time after that. At the end of a year this was all I could do.

"If I rubbed the foot, or put it down otherwise than just flat when I stepped, I was unuble to use it afterward.

"I used crutches all the time at school, so as not to overtire my foot again; but, in spite of all my care, I had that dreadful feeling on the side, and many days the line of pain up the limb.

"Often the foot had fits of shaking, which I could not control."

She continued thus helpless, using crutches for locomotion, and became thoroughly neurasthenic, until June, 1892, when I saw her in consultation with Dr. Romine. We agreed that the diagnosis was clearly the peculiar painful affection of the fourth metatarsophalangeal articulation, and that the other symptoms were probably but those of reflex neuroses; also that excision of the joint offered the only means of relief. However, it was determined first to try the effect of an ointment composed of ichthyol and lanoline, together with fly blisters in the course of the affected nerves. These measures proving of no avail, in July I removed the joint. At the same time it was thought best to divide the tendo Achillis, as the heel had become much drawn up by contraction of the calf muscles, and did not relax even under anæsthesia.

From the moment of operation she never again experienced the old pain, and immediately began to gain flesh and strength under massage, hyper-nutrition, and rest in bed for three weeks. At the expiration of this period she was walking about unaided, and soon was as well and strong as ever. Union by first intention was secured, no weakness of the calf resulted, and the amount of retraction of the toe is about one-quarter of an inch. She now wears an ordinary shoe, and can make almost any exertion without discomfort.

Case II.—N. C., aged thirty-two years, female, servant, native of Ireland. Family history negative. Had always enjoyed good health until October, 1889, when she tripped in going down stairs, and brought her left foot down violently in saving herself. Instantly she experienced an intense cutting pain in the region of the base of the fourth toe. The dorsum of the foot became black and blue, while the whole limb was affected with a dull burning pain. For several days she wore a slipper; then the discoloration gradu-

ally disappeared and pain became more endurable. But she had to cut every shoe that was worn, to prevent pressure upon the painful area. This painful sensation gradually extended from the original location up the front of the tibia, and became very severe in that situation. This misled a prominent surgeon to diagnose periostitis of the tibia, and cut down upon and scrape the bone. She remained in the hospital eight weeks, and was discharged unimproved. In February, 1891, another hospital surgeon cut down upon and chiseled away a portion of the tibia. Again no improvement followed.

Early in 1892 the patient entered the Polyclinic Hospital, willing to submit to anything to obtain relief. At the time she was almost helpless, exceedingly neurasthenic, and had lost much flesh. The scars of the previous operations were very evident. The entire leg was blue and cold and somewhat atrophied, but beyond this nothing was evident except that the fourth metatarso-phalangeal joint and its surroundings were exquisitely sensitive to motion or pressure. From this point the pain was reflected up through the entire sciatic distribution. She was put to bed, and upon a milk diet for four weeks, while local counter-irritants and absorbents were applied, all to but little effect; the old pains and her general nervous condition persisted. I then excised the affected joint, and was amazed at her rapid progress to subsequent cure. Primary union was secured, and in three weeks she was walking about and entirely free from pain. Since then she has entirely recovered her former health and strength.

Case III.—Mrs. E., aged thirty-five years, well-to-do farmer's wife, seen in consultation with Dr. George L. Romine. Family history good. She is of a neurotic temperament, and faints easily. During last ten years she has been subject to attacks of neuralgia, affecting the left forearm. Three years ago she was seized with neuralgia, affecting the second and third fingers of the left hand. There was tenderness in the metacarpal region, whence pains were reflected up the forearm and arm, producing complete disability of the member. The parts were very painful to the touch, and slightly swollen. This condition persisted for four months, and then gradually disappeared. From this time until June, 1892, she remained well, when a marked attack of metatarsal neuralgia, affecting the fourth toe, supervened. This apparently did not follow an injury. The pain became continuous, and resisted all efforts for its relief, except when she laid down, when it would diminish or entirely disappeared. When I saw her, at the end of October, she had become bed-ridden, almost helpless, and exceedingly nervous, but nothing of disease was evident in the foot except the violent, unbearable pain that was invariably produced at the fourth metatarso-phalangeal articulation, upon the slightest pressing together or rolling upon each other of the outer metatarsal bones. At this time, even the weight of a stocking could not be tolerated upon the foot. The pain extended into the peroneal and sciatic nerves. She had lost fifty pounds in four months. The calf on affected side measured one and a half inches less than its fellow.

The affected joint was excised, primary union secured, and she steadily regained her usual health. Pain has disappeared, and she can walk with comfort.

A maternal aunt of Mrs. E. injured her foot eight years ago, and suffered in much the same manner as did the niece. She has never been able to secure relief, and to-day is scarce able to walk across a room without bringing on a severe attack of the pain.

A sister of the patient injured her foot ten years ago, and was then confined to her room for twelve months, because pain developed whenever the member was placed upon the ground. For five years she was unable to walk upon the street, while at the present time she cannot walk far without originating an attack of metatarsalgia, and has to be extremely cautious in walking over uneven surfaces.

Case IV.—Mrs. S. C., aged forty-five years, as missionary, residing in Japan. She writes:

"When out walking in the city of Tokio, Japan, in the summer of 1888, and wearing a new pair of high-heeled shoes, I felt first a slight pain, which soon increased to severity, in my right foot in the region of the fourth metatarso-phalangeal articulation. The pain became so intense that I could walk no further. These paroxysms of pain continued to return with the slightest aggravating cause, the disease gradually becoming worse, so that for two years past, when at home, I have seldom had a shoe on my foot, and was not able to wear the loosest shoe when riding in a carriage, being almost always compelled to remove it after entering. When suffering the most intense pain it was accompanied with a general nervousness of my whole system. Upon removing my shoe all pain and nervousness soon ceased."

I removed the affected joint in May, 1892. In three weeks the patient was able to walk about with great freedom in ordinary shoes, and has since remained free of pain.

Case V.—Mrs. R. T., aged thirty-two years; Canadian; housekeeper. Has suffered for five years from well-marked metatarso-phalangeal neuralgia, involving fourth toe of left foot. No assignable cause. Attacks have been growing more frequent and severe progressively until she became almost invalided. Was compelled to remove shoe regardless of surroundings instantly upon supervention of the attack.

In December, 1892, I amputated the fourth toe together with the corresponding metatarsal head. In three weeks she was walking about as well as ever and has been entirely relieved of all discomfort.

Case VI.—Lizzie T., a Russian; single, aged twenty-two years; mill hand. This woman works the treadle of a machine with right foot. Two years ago began having pain radiating from fourth toe. The frequency and severity of these attacks—necessitating removal of shoe—have increased steadily until she was entirely unable to work and had difficulty in walking.

In January, 1893, she entered the Polyclinic Hospital, and my resident, Dr. M. W. White, excised the affected joint under my supervision. Primary union occurred, and the cure has been complete.

Morton[8] gives the following graphic description of a case of metalarsalgia, written by a medical friend who had been a sufferer form the more severe form of the disease:

"I have suffered intensely from this affection for many years, and in all this time have never found medical man or layman who understood what I meant when I complained of it or alluded to it. It has been pronounced by surgeons who have examined my foot as a subluxation or a malformation of the articular surface of the first phalanx of the fourth toe, where it articulates with the fourth metatarsal bone, the concavity not being sufficiently concave. This I have long been convinced is an error.

"My own sensations have convinced me that the pain is caused by pressure upon a nerve, but what pressed upon the nerve I was unable to tell. The immediate necessity of removing the boot and the relief

8 Loc cit.

afforded by manipulating the foot in a manner learned by experience pointed to a dislocation; but the reduction of the displacement was never sufficiently sudden and marked to confirm the belief that there had been a dislocation.

"Now, after living for more than half a century, practiced my profession for over thirty years, and suffered half my life with an affection not understood and ranked with a disease so trifling as a corn, I find myself enlightened and the mystery cleared up by your valuable paper on the subject.

"The first paroxysm occurred in my boyhood, and was produced by tight lacing of skate straps. On unbuckling the straps, the 'cramp,' as I called it, was at first soon relieved and nothing thought of; but a continuance of this system of squeezing by tight skate straps and tight boots, and riding for hours on horseback with the flexors of the leg and foot in violent action and the toes turned in, the attacks became more frequent, more painful, and the abnormal condition of the parts became chronic. These were in my case undoubtedly the causes predisposing. The causes determining the accession of a paroxysm are the wearing of a badly-fitting boot, especially if the sole be narrow; a long and fatiguing walk, particularly on a hot day over a hot pavement; a long ride on horseback; a wet boot sticking to the sock; a wet sock sticking to the toes; long-continued flexion of the knee-joint, as in a rail-road car, carriage, or lecture-room; treading on an uneven surface, as a cobblestone pavement; and, should the nervous system be excited from any cause, these exciting causes will act more powerfully.

"The symptoms of an attack in my case are most intense pain, 'cutting to the heart,' sickening, a feeling that it is unendurable, faintness, cold sweat, total incapacity for the time of directing the mind or will to any other subject, a horrible increase of torture on the use of the boot-jack; and all this with no redness, no swelling, no abrasion of the skin, no callosity, no visible displacement of bones, at least after removal of the boot.

"The suddenness of the attack is noteworthy. I have been obliged to drop everything and remove my boot, sometimes in company, sometimes in my carriage. I have even been obliged to sit down on the curbstone and remove the boot. I have dismounted from my horse and sent home for slippers before I could proceed. I have tied my horse to a tree and lain on the ground, unable to ride farther.

"I have spoken of a tight boot and of removing the boot, but I have had tight boots which were great favorites, because they would not 'let my toe out of joint.'

"The remedies from which I have obtained relief are removal of the boot and then manipulating the toes—straightening them out. When inconvenient to take off the boot, I have found that grasping the foot tightly round the metatarsal region will answer; and I have sometimes worn a circlet of India-rubber band, binding the foot round the instep. Putting on a dry boot and dry stocking is of great benefit, and the boot should be well sprinkled with powdered soapstone before putting it on. Frequently an attack has been relieved completely without other means than rest and a cup of strong tea."

Morton also reports the following from another medical friend:

"For several years previous to 1864 I had been subject to occasional dislocations of a relaxed joint in the fourth toe of my right foot. They had always occurred in walking, and the symptoms were perfectly distinct; the reduction, which was usually effected without difficulty, by simply 'working the toe,' was equally unmistakable.

"In the summer of that year I was climbing a mountain, when the joint became displaced; and, as it would speedily have slipped out again had it been reduced, I allowed it to remain luxated until I had finished the ascent and returned to the base, when the pain was so great as to make it necessary for me to ride home. After several hours of suffering, the joint gradually resumed its normal state.

"Since that time I do not remember that the luxation has ever taken place; but I have had many attacks of neuralgic pain in the part, coming on generally after exercise, but sometimes after sitting in one position, as in my carriage. Often exercise does not induce it. Heat, as from the pavements or the sand in summer, is a much more frequent cause. It begins gradually, and sometimes wears away in the same manner, but sometimes vanishes suddenly, as if by magic, without

the use of any means of relief. The pressure of a boot always aggravates it; but it has attacked me while in bed at night. Diversion of the mind will often allay it, but it sometimes comes on again afterwards with far greater severity.

"In 1869, while spending most of the summer at Atlantic City, I suffered more from this trouble than ever before or since. It would then often come on at night, after a day in town; and once or twice the attacks lasted more than twenty-four hours. So great was the annoyance from it, that I proposed amputation of the toe to a surgical friend, but he advised me against it. Since then it has been much less troublesome, though I have sometimes had it more or less every day for a week.

"Deep pressure over the metatarso-phalangeal joint is painful, but does not bring on an attack unless long continued. Cold has given me more effectual relief than any other remedy I have tried."

The three following cases are quoted from the same source:

"In March, 1873, I was asked to see Miss H. S., aged twenty-six years, who, while in Europe four years before, had injured her right foot by stepping upon a small stone. She said that she had at once experienced intense pain, which was soon followed by slight swelling and redness. From the date of the injury localized pain continued, especially while wearing a shoe. The pain was referred to the head of the fourth metatarsal bone. There was constant distress in the part, often of a sickening character. After wearing a shoe, pain came on with great intensity. At such times the shoe had to be instantly removed, the least delay causing a paroxysm of great suffering. The boot or shoe had to be removed so often that slippers were substituted. A marked lameness was induced by the patient's endeavor to spare the foot in walking. The pain was confined to the joint of the fourth metatarsal bone with the base of the associated phalanx. Pressure in this region, or rolling the fourth and fifth toes upon each other, caused violent pain which extended up the limb. It was severe when pressure was made upon the base of the first phalanx of the fourth toe, which could be prominently felt in the third and fifth toes."

"Dr. H. W. Alison, of Hagerstown, Maryland, called on me in the spring of 1875, seeking relief from neuralgia in his right foot, which had existed for years, and was gradually getting worse, and stated that he was willing and ready to submit even to amputation of the leg. He gave the following history:

"About six years ago I experienced an unpleasant, painful sensation in my right foot, which possibly originated in a strain: the pain was first observed in the fourth metatarso-phalangeal region; in the course of a fortnight it was followed by most violent pain, which was simply unbearable and so severe that it terminated in a convulsion. A painful condition of the parts followed, and with the least provocation (wearing a shoe or boot), sometimes without known cause, paroxysms of intense pain returned at various intervals, lasting from one to forty-eight hours. The pain, with one or two exceptions, has been confined entirely to the section of the foot indicated. My suffering has been beyond all comprehension; very often I have been compelled to jump from my carriage or stop while walking, remove my boot, which has always been of ample size, apply ligatures to the limb or foot, use hypodermic injections of morphia, frictions, or call upon some one to assist me by standing on the foot. This affliction has been the burden of my life, and this burden has been increased after consulting many eminent medical men, who gave me no satisfaction as to the nature of the disease, nor even suggested a hope of relief. My health otherwise has been uniformly good. I am satisfied the cases you have had are similar to my own, save in the intensity of my sufferings, and I shall gladly submit to the operation you have suggested."

Mrs. C. H. K., of this city, a lady fifty years of age, gave me the following history: "'The queer feeling,' I have been accustomed to call it, which has been in my left foot for thirty years, is a painful condition. The pain is in and about the joint of the fourth toe, with occasional attacks of intense suffering, when the pain extends to the knee, and if my shoe is not instantly removed when the attack comes, the pain reaches the hip. It does not matter whether I wear a large or a small shoe, as I have never worn a tight one, but it seems that the least pressure will produce the same result. Often my

sufferings have been exceedingly acute, and come on without any warning. Once I was taken while walking in the street, and the agony was so great that I was compelled to rest on a stoop, remove my shoe, and walk some distance in my stocking alone, the pain running in a straight line to the hip joint. In September, 1868, while at the Academy of Music, I had an unusually severe attack, and, not removing my shoe as quick as I should have done, was obliged to walk to my carriage without the shoe, and suffered intense pain for three hours. My eldest sister has been similarly affected still longer than myself, but in the right foot, same toe and joint. She has several times given up wearing shoes, but the attacks continued."

Charles K. Mills[9], in a lecture upon "Pain in the Feet," relates the history of a typical case that was entirely relieved by the operation of Morton. A woman, in jumping upon rocks twisted her foot. The foot apparently was not injured, and she was soon about as usual. During the next two years, at intervals of from two to eight weeks, a peculiar pain in the foot would develop that would last two or three days. Two years later she injured the foot again in the same manner. After this the pain was seldom absent more than a few days, and each recurring attack was of increased violence. Again, two years later, the pain became almost constant. The pain was a dull, heavy, sickening ache, from the foot to the hip, and with a sharp pain through the foot. At times the ache would be limited to the foot, but the sharp pain was there constantly. Arising in the morning, the patient could not put her weight upon the foot until she had taken hold of it suddenly from the top and pressed it hard together, and held it in both hands with all her strength for some minutes. After exhausting every known local and general remedy, the fourth metatarso-phalangeal articulation was excised. The patient subsequently slowly became free of every vestige of the former pain, and was entirely restored to health.

Poullosson[10] describes an instance where a medical man, twenty-nine years of age, had suffered from this affection for some years. It gave no trouble when the foot was at rest and without a shoe, but was usually brought on by wearing boots and walking a good deal. It was much more likely to occur in going down than in going up a hill. The pain came on suddenly, a feeling of something having given way in the foot accompanying the onset, together with a kind of grating sensation. After this the patient walked lame, for all pressure of the anterior portion of the sole of the foot to the ground was painful. If walking was persisted in the pain increased, till in a few moments it attained its maximum, rendering all further attempts at locomotion impossible.

Edmund Roughton[11] has reported the following case:

"A medical man, aged thirty-three years, complained that for eighteen months he had suffered from attacks of burning pain in the forepart of the sole of the left foot. The pain occurred several times a week, and was usually brought on by prolonged standing or by walking any considerable distance, and was so severe as sometimes to cause him to remove his boot and grasp the sole of his foot with his hand. On examining the foot, I found that the transverse arch formed by the heads of the metatarsal bones had sunk, so that a distinct convexity replaced the concavity normally found in this situation.

"In this case the patient had increased considerably in weight during the period of development of the symptoms, and his transverse metatarsal ligament had presumably been unequal to the increased strain."

E. H. Bradford[12] has reported a series of thirteen cases, none of which, however, were severe enough to demand operation. In these the symptoms were not in a single instance the result of traumatism, nor was any evidence of dislocation or other local change observable. These patients were all in enjoyment of excellent health, and in none were there evidences of gout or rheumatism.

Treatment.—The less severe forms of metatarsalgia may often be prevented from running into the more serious types by proper shoe construction or by wearing a narrow flannel bandage about the ball of the foot. Morton, whose suggestion

9 Journal Nervous and Mental Diseases, vol. xv. p. 4.

10 Loc. cit.

11 London Lancet, March 16, 1889, p. 553.

12 Loc. cit.

the latter is, directs that the bandage be two inches wide, and long enough to wrap neatly and firmly about the metatarsus some five or six times. The end is pinned, and the stocking drawn over. This has given marked relief in a number of cases.

The shoes for persons suffering from this disease should be firm-soled, make no lateral pressure upon the metatarsus, yet have the instep tight enough to prevent the foot slipping forward. The great object of the shoemaker should be to prevent pressure, either lateral or antero-posterior, upon the metatarsal arch, and also to prevent any rolling motion of the outer metatarsal heads upon their fellows. A broad, rigid sole would appear to best fulfil this last indication. Bradford proposes the use of digitated stockings in these cases, with a view of keeping the toes further apart. As the foot spreads when the weight of the body is thrown upon the member, it is apparent that the patient should be standing when the measurements for shoes are made, as has been advised by Grün.

The use of various pads in the shoe and about the toes, also such measures as the hollowing out of cavities in the sole opposite one or more of the metatarsal heads have been tried, but invariably found unsatisfactory. A variety of the affection calling for so much attention to secure comfort would clearly demand the certain cure to be afforded by operation.

In persons where rheumatic or gouty diathesis may be suspected appropriate remedies for those disorders should be given a thorough trial before operative measures are resorted to. But when the condition is entirely of local mechanical origin the employment of general or local medicinal agents is useless. On the other hand prolonged rest in bed will benefit all cases more or less, and occasionally secure relief for long periods, or even permanently cure the milder phases of the disorder.

Operative treatment should be limited to the metatarso-phalangeal articulation from which the neuralgia radiates, or, perhaps, to amputation of the corresponding toe above the joint, as have been recommended by Morton, and endorsed by other writers. These procedures are among the safest and simplest in surgery. Of amputation of the toe, together with its metatarsal head, nothing more need be said than that by this measure the possibility of subsequent trouble arising from a tendency of the toe to retract and ride above or below its fellows is excluded. However, this heretofore occasionally troublesome sequel can be avoided by dividing the extensor and flexor tendons while excising the joint, as I have done in five cases with most satisfactory results.

Operation.—Primary union should be aimed at. To secure this the foot must be scrupulously cleansed. The nails should be trimmed short. Then soap, water, and nail-brush be liberally applied. Following this the member should be soaked in 2½ per cent. carbolic acid solution, and finally dressed in a moist carbolic dressing of the same strength until the surgeon is about to operate. Where the foot is especially foul it is my custom to finally dip it into a saturated solution of permanganate of potash until colored to a dark mahogany hue, and then transfer it to a saturated solution of oxalic acid until decolorized, before applying the temporary dressing. When the surgeon is about to operate the temporary dressing is removed and the parts given a final douche with 1:1000 sublimate solution.

A vertical incision from one and a half to two inches long is made, beginning over the proximal inter-phalangeal joint and extending upward in the centre line of the toe.[13] The extensor tendon now comes into view, and is divided. Another stroke of the knife carries the incision through its entire length down to the bone. The handle of the knife or other moderately blunt implement is then employed to separate the tissues from the upper and lateral portions of the joint. Next the blades of a powerful sharp pointed, narrow bladed, cutting pliers are pushed down on either side of the phalanx immediately below its base (hollow of the blades always toward the articulation), and this bone divided. The metatarsal bone is then similarly divided just above its head. The separated joint is then seized by bone forceps and dissected away from any remaining attachments. This done, the flexor tendons will be seen lying at the bottom of the wound, and should be picked up by forceps and divided with

13 This joint has also been excised through an incision in the sole, but the method is objectionable on many grounds.

scissors. If hemorrhage is severe and not controllable by moderate compression of the parts, ligatures should be applied. I have never had occasion to apply a ligature in this operation, as the pressure of the dressing has always sufficed to control any oozing that might continue after the sutures had been applied. The wounded edges are next to be approximated—no drainage being required if asepsis has been maintained—by continuous or interrupted suture, as may be preferred. A gauze and cotton dressing is finally applied and bound firmly on with a wet gauze roller, care being taken to place little pads of gauze in such positions as will hold the toe in its proper position during healing.

The foot should be kept considerably elevated for the first two days, after which it may be brought to the level of the bed. I prefer my cases to remain in bed or on a couch until the fourth or fifth day, when they may be permitted to sit up with the foot resting on a chair. At the end of a week the sutures are removed; two or three days after which the patient is permitted to move cautiously around, while at the termination of three weeks all restraint may be removed and a firmly healed wound and permanent cure confidently expected. No special form of shoe or care of the foot is afterward required.

In case suppuration should arise in the wound, the sutures should be at once removed, the wound cavity washed out with full strength peroxide of hydrogen solution, then with $\frac{1}{10\,00}$ corrosive sublimate solution, and gently stuffed with iodoform gauze. All of which should be repeated every one or two days until the wound closes by granulation.

STRYCHNINE VERSUS ERGOT IN OBSTETRIC PRACTICE.

G. V. HALL, M. D., LL. B., Wheaton, Texas.

About a year ago I was called one morning to attend a case of labor four miles in the country. Upon arriving at the house of my patient, whom I had attended the four previous labors and who was subject to severe hemorrhage succeeding delivery, I found the child about to be born. Shortly labor terminated in the delivery of an eleven-pound boy and an alarming hemorrhage immediately followed. I made firm pressure and manipulation over the fundus uteri with my left hand and gentle traction on the cord with my right when, to my dismay, the cord came away leaving the placenta in situ. Without delay I introduced my hand, which was surgically clean, up into the uterus, removed a lot of clots and peeled off an adherent placenta intact.

I think the wrapping of the cord several times about the child's neck made such a pull on the cord at the moment of birth that it was then almost detached, my slight traction only completing it; so easily did it come away.

An attendant handed my obstetric bag. I looked for my ergot (I always carry a vial of the normal liquid ergot, P. D. & Co., with me, as I find that preparation the most reliable and convenient for use by mouth and hypodermically) and to my discomfiture found I had left the bottle at the house of a patient attended the previous night. A rapid inventory of suitable remedies at my command discovered but two indicated: strychnine sulphate and laudanum. With the action of the former on the uterus I had had some experience—the latter I had never used in such a case though frequently seen it recommended. So I hastily chose the strychnine and administered to my bleeding patient three tablets of one fiftieth grain each. She was complaining of being "blind" etc. In a few moments, aided by my gentle friction of the uterus,

contractions sufficient to check further bleeding ensued and there was no more from that on—though no other dose of medicine was given during the three hours that I watched the patient.

Acting upon the suggestion above stated I have substituted strychnine sulphate (S. & D.) for ergot in the last fifty cases of labor, and with such gratifying results that I believe I have made an advance in my very humble and imperfect therapy. At least, I see no reason to return to the use of the unstable and uncertain, though time-honored ergot. Are my views iconoclastic? Dare an obscure country practitioner raise voice or pen against an idol that has well occupied a niche in the holy of holies of obstetric science "Since the time whereof the memory of man runneth not to the contrary?"

That we may show a reason for the faith (in strychnia) that is in us let us examine and compare briefly the properties and action of these two drugs whose use is as universal as the practice of medicine and perhaps as little thought about.

"*Strychnine Sulphate:* a white salt; in crystals, readily soluble in water," etc.

"*Ergotin* (I take this as a type of alkaloidal strength though it is not an active principle) is simply an aqueous extract. It varies much in strength, owing to faulty methods of preparing it, and, as found in the shops, is frequently inert. * * * * It is the most eligible preparation for hypodermatic injection." (Bartholow.)

"Many of the so-called active principles have been isolated by chemists, and named ecbolic acid, ergotic acid, schlerotinic acid, and ergotin. None of them represent the entire drug, the nearest in approach being ergotin." (Hare.)

In the classifications of the therapeutic authors in my library, from Headland to Hare, strychnine is classed as first in importance amongst the excito-motors. Ergot follows as third in some lists, fourth and seventh in others. A thoughtful author writes: "Ergot itself is very variable" (and this gets at the *meat* of the matter) "even when fresh and living, and even at the present there is scarcely any view of * * * its physiological action * * * which is accepted by all experimenters."

"Ergot and all its principles deteriorate rapidly with time, and lastly the experiments upon it have been conducted during the past half century by a great many investigators, with almost as many different preparations." (Prof. Bolles; Ref. Hand-book Med. Sci.)

If the composition of the drug is so wrapped in doubt what must its action be? And ergot in obstetric practice is not a drug for to-day or to-morrow, but *now*, in the living (*or dying*) present.

In the fall of 1884 I was summoned unexpectedly to attend a woman in labor. I had never before done any practice for this family and knew not of them. This was the patient's fifth confinement, and I learned from her mother a few moments before the child was born—for I had been tardily called—that she had narrowly escaped death from postpartom hemorrhage in the previous two labors; in which, however she had been attended by one whom I knew to be a very careless practitioner. Hence I laid the flattering unction to my soul that I could perhaps vary the usual current of affairs post partum and prevent the loss of blood detailed. Vain hope! the most fearful hemorrhage that I have ever seen followed the spontaneous expulsion of the placenta. It fairly rivalled our honored Professor Wallace's cadaver-bladder-scalpel-potass solution-water pouring drama (familiar to all old Jefferson men—and a valuable object lesson it was, too).

Despite the most judicious management of the case secundem artem—ergot, and a good (?) preparation too, by the mouth and under the skin *ad lib.* and *p.r.n.*, accompanied with external manipulation of a most flabby uterus, etc., etc., in spite of each and every effort directed to her relief, she bled until she was blind, pulseless and almost exsanguineous. From what seemed veritably the jaws of death she gradually wandered back to this vale of tears; saved, I doubt not, by the prayers of her devoted mother—for the effect of my remedies seemed *nil.* Her convalescence was marred by almost every complication incident to extreme anæmia; but she lived to bear two more children before leaving my field of practice. I impressed upon her husband, a very intelligent man, the importance of a prophylactic treatment should his wife again become pregnant, and during the fifth month of her succeeding pregnancy he applied to me. I put

her upon strychnine sulphate in aquæous solution, grain $\frac{1}{20}$ t.i.d. on alternate days up to the ninth month, when I increased the dose to grain $\frac{1}{16}$ and directed its use three times daily.

I saw no more of her until I was called to attend her in a precipitate labor—the child being born just as I entered the room. With the exception of the dose of strychnine taken as usual (which happened to be at the inception of the unexpectedly sudden labor), not a dose of medicine was administered. The hemorrhage was less than that of a normal labor, much to the patient's surprise and my own satisfaction. The solution was continued daily during the puerperium, and involution and convalescence were rapid and uneventful.

I had learned in the meantime that this patient had for some years been in the habit, at the suggestion of a medicine-wise friend (?) of indulging in frequent potions of a good quality of fluid extract ergot from a six-ounce vial which she kept in her possession, thus hoping to rid herself of the unwelcome burdens of matrimony. Consequently I gave her favorite beverage a wide berth; well knowing at this time what I knew nothing of in my former experience with her, that, in therapeutic effect, ergot was to her as water to others. A discovery which perhaps explained the impotence of my former heroic dosage.

On this hint I since have acted, and in the score of "flooders" whom I have been called on to treat in the past eight years, I have been gratified and sometimes astonished by the almost specific action of the salts of strychnine upon the uterus; especially in the pregnant state.

A lively, and at times heated discussion as to the exact physiological action of ergot has continued through many years up to the present.

Prof. Hare, who is probably our most scientific investigator in the physiological action of drugs, avers his belief that Hemmeters studies prove that ergot causes uterine contractions by stimulating the lumbar centres rather than as a stimulant to the uterine muscle; in other words that it acts as an excito-motor direct. This view I have always believed to be correct; though no observing clinician can deny that in certain parts of the body—and perhaps to a certain extent in all—it contracts the arterioles through vaso-motor action. But I believe this action to be secondary, incidental and, as regards the uterus, of only comparative importance.

I was once as firm a believer in the specific action of ergot upon the uterus as of quinine upon malarial poisoning, but I now assert that the claim of ergot as a uterine stimulant rests upon emperical observations made in the dark ages of therapy long antedating the era of the study of physiological actions; and I maintain that at the present stage of modern obstetrics, when external manipulation of the uterus in cases of inertia is playing so large and important a part, it is impossible in the conjoining of drug and hand to decide to which the meed of praise belongs.

Incidentally I have found fifteen drop doses of normal liquid ergot repeated half hourly, for 3 or 4 doses, valuable in increasing the efficiency of lagging pains and, when alternated with vinum ipecac into drop doses every fifteen minutes, it is serviceable in lagging pains, rigid os and dry surfaces. Here its use has a value and is attended by an appreciable result; but at that critical moment in the phenomenon of labor when its aid is most invoked, when precious life blood is fast ebbing, I firmly believe that its effect is as uncertain as is the stability and nature of its composition. Almost all patients loathe its nauseous taste. (And if the palate rebels at a fluid extract how must it recoil at "15 or 20 grains of the freshly powdered drug in water"—an old proceedure whose revival is warmly recommended by a late authority?) I have seen many patients vomit it almost immediately who were not previously nauseated, and the relaxation attendant upon emesis did more of harm than the ergot ought to have done of good. It is not pleasant nor profitable to have a patient so nauseated by one's own act as to compel a resort to external manipulation of the uterus while the patient is vomiting and lying upon her side or belly.

The points I have humbly endeavored to present are these: Ergot is a most nauseous drug, the strength and stability of whose various preparations are matters of grave doubt or conjecture.

In so great a degree is this true that the potent and marvelous chemistry of the present, rivalling, as it does, the magic of the alchemist's art in years lang syne, has failed to penetrate the mystery of its alka-

loidal powers if such there be. So I take it that P. D. & Co.'s Normal Liquid; Squibb's fluid extract and S. & D.'s Ergotole have done the drug full justice, and represent all of value there is in its composition known at the present day. Strychnine is a non-nauseous and quickly absorbed scientific alkaloid which can be kept without loss of strength for years. It is in the hands of every practitioner, in exact dose, in hypodermatic tablets, for quick and ready use by mouth or needle. It is the ideal excito-motor—the type of the whole group. It has a distinct triple action: invigorating and sustaining the action of heart, of lungs, of uterus: a most valuable and timely aid in preventing and in relieving shock from hemorrhage or other cause. *Its action upon uterine contractions is specific.*

SOCIETY REPORTS.

SURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, March 13th, 1893.

Dr. W. L. Rodman, President *pro tem*, in the chair.

PERFORATIVE SHOT WOUND OF ABDOMEN —OPERATION—RECOVERY.

Dr. A. M. Vance: The seventh day of last February this patient, thirty years of age, was shot with a 32-calibre bullet in the left side of the abdomen five inches to the left and on a line with the umbilicus. I saw him within a very short time —probably a half hour—afterward. He showed evidences of very marked shock, evidence of being greatly impressed and I had him removed carefully to the Norton Infirmary, opened the abdomen as quickly as I could and found two complete perforations of the ileum, two of entrance, two of exit, also one of the mesenteric border of the ileum. Suturing was rapidly practiced and he was gotten off the table really in better condition than when he went on. A glass drainage tube was left in the lower angle of the external wound for forty-eight hours, drainage was very considerable. The man has made a rapid and satisfactory recovery. He was up walking about the Infirmary at the end of the second week, has lost very little strength or flesh. On the fourteenth day he was given a purgative. For five days he was starved to allow rest of the alimentary tract. The lower bowel was emptied by enemata; he has not had an untoward symptom and is about well now.

DISCUSSION.

Dr. W. L. Rodman: How long after the shot before the bowels were allowed to act?

Dr. A. M. Vance: I think I relieved the bowels by enemata at the end of forty-eight hours just for comfort.

Dr. W. C. Dugan: How long after taking food was he shot?

Dr. A. M. Vance: I do not know, but he had probably been eating considerable, because he vomited on the table an enormous quantity. And the intestines were filled with feces.

Dr. W. C. Dugan: Was there any fecal matter in the cavity?

Dr. A. M. Vance: I could find none in the cavity; it was very thoroughly washed out, in fact the major portion of the time consumed in operation was in irrigation, getting rid of material vomited, and reading of the intestines. I used the continued Lambert suture of catgut supported by resuturing, the ends of suture being tied together.

I think it is very important in these cases of section, especially in men, that a bandage should be worn for a long time to support the cicatrix. I think herniæ are more likely to take place after laparotomy in men than in women. This may be accounted for by the greater convexity of the abdomen, aud consequent increased strain.

Dr. H. H. Grant: What was the temperature after operation?

Dr. A. M. Vance: I do not believe the temperature was ever over 100° F. The pulse ranged along about 90 for the first week then came down to normal. He was starved absolutely for three days; for a number of days more he only received consomme, and for several days following he was only given eggs. I have come to the conclusion that egg raw is the best thing that can be given after operations of this character.

Dr. Geo. W. Griffiths: I think Dr. Vance is to be congratulated upon the very marvelous result of the case, it would have been a necessarily fatal one I should say without operation. I operated upon a case of the kind two or three years ago where there were several perforations of the intestine; in this case there was a concealed hemorrhage about the spinal region which could not be controlled, and the man died thirty-six hours after operation.

Dr. W. C. Dugan: Certainly Dr. Vance is to be congratulated upon the results obtained in this case. I am rather surprised that these cases have always been fatal. You will remember two papers in the *New York Medical Journal* by Stimson, where he reported up to that time all the cases he had been able to get the history of in America. In this valuable contribution he compared the results of those cases operated on with those left without operation, and the conclusion of this painstaking surgeon was in favor of non-operation. The mortality in the cases operated upon was 87 per cent. and the cases that were left and treated purely by the expectant plan 83 per cent. He concluded his discussion, however, in his last report by stating that while the mortality was in favor of the non-operative procedure, he would under favorable surroundings operate even in face of such evidence. That coming from Stimson, a conservative man—yet a bold surgeon—I think should not be passed over lightly.

Now in regard to the late war—while we are not to be governed by statistics compiled in these pre-antiseptic days, they have been referred to in previous discussions so I take the liberty of calling attention to this here, as they have some bearing on the subject, since they show the result of the non-operative treatment. Otis states that there is no case on record of gun shot wound of the small intestines that recovered. In gun shot wounds of the stomach there were a number of cases on record of recovery, and of the large intestine under 80 per cent. terminated favorably. I have two cases of gun shot wounds of the intestines to report, and they were both fatal. They were both cases of perforative wounds, and both patients died in condition of shock. Certainly the case reported by Dr. Vance is one of extreme interest, and the reason of this happy result is that he operated at once before extravasation of fecal matter into the peritoneal cavity had taken place, and had his patient in an Infirmary thereby having the advantage of Hospital service. I do not wish to be understood as standing here advocating "the let alone" plan of treatment. I would have done exactly what Dr. Vance did. We are confronted by the startling fact that most all these cases die after operation. We cannot promise the patient much. The mortality in Louisville has been—with this case of Dr. Vance's excepted—100 per cent. In conclusion I wish to say: That all cases coming under observation soon after the injury with favorable home or hospital surroundings, where the surgeon can command the services of good assistant and nurse, should be operated on—otherwise leave them alone.

Dr. H. H. Grant: It seems to me that in the present understanding of these cases, the light in which surgery has put them at the present day, such cases as those spoken of by Dr. Dugan and the one reported by Dr. Vance, are understood by all surgeons to imperatively demand an exploratory incision even if there is a possibility that the intestine has not been perforated. I do not think the statistics Dr. Dugan refers to are of much value in the light of present progress of surgery, and I think that conservatism would hardly be the term that would be applied to any surgeon who would hesitate to operate under conditions that were at all favorable, it would rather be cowardice. There can hardly be any question at the present day but the wisest plan is, if there is any doubt about there being any perforative wounds, to explore through the wound itself with the finger until perforation is determined and if that perforation is found to be in a favorable situa-

tion, enlarge the wound to a complete laparotomy or complete the operation by making another incision in the median line as Dr. Vance did. Where there is any question as to perforation going through the abdominal wall, it is easily settled by exploration by the finger. Four or five years ago there was some question about the size of a bullet and the point of perforation; a small bullet penetrating the abdominal wall above the umbilicus was looked upon by some surgeons as not indicating an absolute necessity for operation. A larger bullet in any situation and all bullets penetrating below the umbilicus were marked by many surgeons, especially by Wyeth, as demanding investigation by abdominal section. At the present day, however, I believe that the surgery of laparotomy has been rendered so safe under such conditions as we are able to command in nearly every case, as to make it little less than criminal for a competent surgeon to hesitate to open the abdomen with view of determining whether perforation of the intestine has occurred. Where perforation of the intestine has occurred by almost any bullet that is used by any weapon at the present day, the certainty of fecal extravasation is almost absolute. Where fecal extravasation has occurred a fatal result will almost invariably obtain. Where one of the larger vessels of the mesentery is divided, or important viscera wounded, fatal hemorrhage will be almost sure to result and if any thing should happen to control it, sepsis, even if there were no perforations of the intestine, would be a very imminent danger. I am thoroughly impressed with the belief that the danger of an exploratory operation if it be properly conducted, is almost nothing, in comparison to the immense risks that the patient is subjected to without this operation. And I think it is hardly wise, and perhaps upon second thought Dr. Dugan will agree with me, to consider these old statistics in view of the present status of surgery.

With respect to the operative steps: It has been my preference in suturing all the viscera of the abdomen to use silk rather than cat gut, because I believe it is more certainly rendered aseptic, it is easier handled, and very fine silk can be used, perhaps finer than cat gut and it is easier of manipulation.

It is true that small perforations of the small intestine by a small bullet have been known to close up by swelling without the escape of fecal matter into the cavity; under these circumstances if no vessel were injured, it is possible the patient would recover without operation. In the majority of cases, however, where any bullet, even the small twenty-two caliber, has entered the cavity it is probably a hopeless expectation to look for any other result except fecal extravasation, and practically the result of fecal extravasation is invariably fatal, without abdominal section. In some instances where large laceration of the abdominal wall has occurred, fecal extravasation might be prevented by external escape and might suggest the propriety of establishing a permanent fecal fistula; I feel quite sure, however, that it is scarcely wise to discuss this in surgery, as it is too rare to be practical.

Dr. I. N. Bloom: Given a case where a man has been shot below the umbilicus into the belly at short range with a large caliber revolver, and the patient, after going through a protracted illness recovers —say after three week's illness, some fever and slight evidence of peritonitis—there was no operation or exploratory incision of any kind. Would you come to the conclusion that the intestine had not been perforated?

Dr. W. C. Dugan: If there were any evidences of peritonitis, I should conclude that the intestine had been perforated.

To illustrate a point I made in my former remarks: I remember the case of a little boy who was accidently shot with a thirty-two caliber rifle through the abdomen, the bullet entering just to the left of the umbilicus ranging through and coming out just in front of, the kidney on the opposite side. A young physician was called, a man who had never performed or assisted in a laparotomy. He told the family that the boy would certainly die, that there was absolutely no question about it. He urged upon them the advisability of an operation, but with the meagre chances he suggested of recovery they would not consent to it. That boy recovered and was about his play at the end of a week.

That young man was a good physician, but if he had opened the abdomen in this case, inexperienced as he was, I hardly think there is a surgeon present that would question the patient's chances of recovery.

The operation would certainly have been very grave indeed, without surgical surroundings, without hospital advantages, and without surgical experience. The patient would most likely have died with the operation, whereas he recovered without it. We should not judge hospital cases by those we have on the outside. Any surgeon is liable to be called to see a case in a negro hovel for instance, where the patient will not go to the hospital, and if operation be performed in such a case with the decidedly unsurgical surroundings, with nobody to nurse the patient afterward, I believe death will result in 99 if not 100 per cent. of all cases, and it will simply be a stigma on abdominal surgery. I should like to go on record as stating that the majority of these cases should be operated on if they could be placed where they could be cared for, otherwise I think the operation should be discouraged.

The statistics of Stimson, (who is one of the greatest surgeons in the world) compiled since the day of antiseptic surgery, show that the mortality is four per cent. in favor of non-operative work. We cannot afford to turn our backs upon the statistics of such a man as Stimson. Ideal surgery is not always the best surgery. It is the best surgery that saves the greatest number with the least facility —with the least amount of suffering.

Dr. H. H. Grant: I believe Stimson states in his papers that a number of cases recovering were not verified by any positive evidence of there having been a perforation. A great many of them did not have any verification of it, consequently the mortality of his report should not be considered, except in so far as there is positive evidence of perforation. The position I took, (and the position I think we all ought to take with respect to surgery) is that it should not only be in competent hands, but in safe surroundings. Of course we cannot expect to instruct people who are too ignorant to give an emetic or an injection in the treatment of conditions where it is absolutely demanded, to locate brain tumors and do hysterectomy—still it would be folly not to teach that this is the proper method of treatment when in order, and we take the position that we are excusable in allowing such neglect of treatment, if we fail to urge upon the authorities to put such conveniences and facilities around a populace as safety and security demand. I think we ought to teach what is right; we ought to teach principles, and not make allowances that are inexcusable and unscientific, which will allow a loop-hole for ignorance or even criminal neglect. What I said was in support of a surgical principle not isolated cases, and not supposed to be any exception to that universal law, "that there is no rule that has not an exception." The principle I mean to advocate is that if a surgeon has a case of gun shot wound into the belly, he should not waste precious time in futile conservatism, not that he would be expected to take a pocket knife and slash open the abdomen and sew up the cuts with a dirty string—what I meant is the principle that it is our duty to advocate operative interference in all conditions of this kind, and not be misled or be dissuaded from operation by the consideration of statistics that I think scarcely have any bearing in the present advanced state of surgical science. I do not mean to under-estimate anything that Stimson says, but I do mean to say that in this particular there has been a marked advance in surgical science and it will only be perfected when the principle is impressed upon those who are beginning to practice surgery and who are being taught it.

Dr. W. L. Rodman: There is perhaps no subject at the present day that surgeons are more in doubt about than they are as to what they shall do in cases of wounds of the abdominal wall, whether they have penetrated the cavity or not. Now, it seems to me that the first thing to do in either a stab or shot wound is to satisfy yourself beyond any doubt as to whether or not you are dealing with a penetrating or non-penetrating wound of the cavity. I think that the symptoms in these cases will generally be misleading. We will not always find shock and other symptoms that sometimes present themselves after shot wounds of the gut particularly, and I am one of those persons who believes very much as Dr. Grant does. I think that in all shot or stab wounds of the abdominal wall, I do not care if there is entire absence of all symptoms indicating perforation of the cavity, it is at least the surgeon's duty to disinfect his little finger thoroughly—not use a probe because it is very easy with it to convert a non-pene-

trating into a penetrating wound—and carefully examine so as to determine beyond a doubt whether or not the cavity has been opened. If necessary the external wound can be sufficiently enlarged to admit of free exploration with the finger. Now having ascertained that the cavity has been penetrated, especially if you are dealing with a shot wound as we are discussing to-night, I believe that statistics all prove that 99 times out of a 100 some one of the important viscera will have been injured, and I fully agree with Dr. Grant that it is our duty to do a median laparotomy and search for the injured viscera and repair it. I believe this is what we should do in every case.

Concerning the statistics that have been referred to to-night: Of course memory is uncertain, but I am of the opinion that Otis makes a stronger statement in regard to shot wounds of the small intestines than Dr. Dugan gives him credit for. Unless I am very much in error he makes the statement almost in these words. "There is no incontestible case of recovery on record, of all the men shot during the War of the Rebellion, after wound of the small intestine." Abernethy said that, "Nature will do nothing for these cases, but leaves them to their fate." Otis does say in the same connection, however, as Dr. Dugan has remarked, that there were a number of cases of wounds of the large intestines that recovered during the war. Of course we know that most of these cases shot during the war may have been shot with minnie balls or very large bullets, consequently would have very little chance of recovery, whereas a man shot with a 22-calibre bullet would have a better chance to get well; fecal extravasation might not take place after injury with a 22 bullet. I can well understand how some of these cases will get well, but I agree in the main with Dr. Grant, that while admitting the possibility of shot wounds of the small intestines getting well when they have been made by a small bullet, at the same time I believe that the dangers of fecal extravasation and peritonitis are greater than the dangers of laparotomy. I have had four cases of shot wounds of the intestine, only one of which recovered.

No. 1.—The first case I operated on in the city Hospital early in 1887; this was the first case operated on in the city of Louisville, or so far as I know south of the Ohio River. The man was shot in the right side above and midway between the umbilicus and the liver. He had been in a fight in a bar-room one Sunday morning about two o'clock; I had him sent to the city Hospital and as soon as I could make arrangements did a laparotomy by candle light, as we had no gas in the hospital at that time. I found the left end of the left lobe of the liver loose in the peritoneal cavity; found two wounds of the small intestine, and a large quantity of blood in the abdominal cavity. I repaired the wounds of the intestine as promptly as I could; there was no bleeding from the torn surface of the liver so I let that organ alone, stitching the capsule with fine cat gut. This man died of peritonitis in about twenty hours after the operation.

No. 2.—The second case was in a mulatto boy about sixteen years of age who was sent to the city Hospital, having received a wound to the right of the median line midway between the umbilicus and the left anterior superior spinous process of the ilium. Drs. Vance and Cartledge came in at the time and saw the case with me. A median laparotomy was done and two large wounds of the gut were found, one of them large enough to permit extravasation into the peritoneal cavity of a considerable amount of fecal matter and along with the feces an *apple core* which the patient had swallowed. This patient lived, so far as I remember, thirty-six or forty-eight hours.

No. 3.—The next case I saw was a negro sbout twenty-six years of age, who was brought to the city Hospital on Christmas day, 1891. I found a wound just over the bladder; the *interne* at the hospital thought the bladder was injured, I did not think so. A median laparotomy was performed after exploring the wound with my little finger and satisfying myself that the cavity had been opened. I found seven complete perforations and two incomplete wounds of the small intestine. These wounds were all repaired very promptly as I had good assistants. This man was not on the table more than thirty or thirty-five minutes. I completed the operation in less time and more satisfactorily than any I had ever done before. During the time I was operating I noticed a white, flaky fluid which would occasion-

ally come out of the abdominal wound, and I remarked to the assistant that I thought the patient must have had tubercular peritonitis, as I could not understand that flaky stuff coming out of the peritoneal cavity. The man was put to bed in good condition, little or no shock. When I made my round the next morning I noticed what seemed to be pus discharging from the drainage tube. On examination it proved to be the flaky-looking material which we could not understand at the time of operation; the *interne* said that quantities of it had passed during the night. I said then that I believed the man had a lumbar abscess which the pistol bullet had opened, and that explained the peculiar looking fluid. The discharge from the drainage tube was unquestionably pus, there could not have been any doubt about it. The man developed peritonitis at twelve o'clock that day and died late in the afternoon. We made an autopsy and found that my suspicions were correct in regard to the lumbar abscess. All of the wounds in the intestine had closed perfectly; there was no great amount of inflammation around the wounds; the intestine was tested by the water test and all of the rents were seen to have been completely closed. We found in the peritoneal cavity a large quantity of pus, certainly not less than one and one-half pints or a quart; then searching further back, we found that the bullet had entered a lumbar abscess which had partially emptied itself into the cavity. This man was the first and only one of the three that I thought had any chance of recovery; I believe that he would have made a good recovery notwithstanding he had seven complete wounds of the intestine, had there not been this unique feature in the case—the bullet penetrating a lumbar abscess, the pus pouring into the peritoneal cavity and causing peritonitis.

No. 4.—I was called by Dr. W. Carroll Chapman the day after operating on the case above reported, to see a case down town that had been shot on Christmas day. I found a negro girl about fourteen years of age that had been accidentally shot by the discharge of a pistol in the hands of a cousin of hers, the bullet being rather large, probably a 32 or 38-caliber. The ball had entered below the middle of the crest of the ilium, ranging downward; I could trace it down to the sacro-sciatic foramen and it had gone into the pelvis at that point. I found the child on the morning of the 26th with high temperature—105½° F.—pulse very frequent; belly tympanitic. I asked the question if she had passed bloody stools, and they said she had passed two or three tablespoonfuls of blood a few minutes after being shot; she later had an action of fecal matter and it was freely tinged with blood. So I have no doubt in the world that the intestine was injured in this case. Not seeing the patient, however, until the next day, and the child already having a tympanitic belly, and other symptoms which led me to believe that the time for a laparotomy had passed, I concluded to see what this case would do without it. The wound was freely enlarged, irrigated and plugged with iodoform gauze. I thought that I could detect a fecal odor to the discharges coming from the wound. We let the case alone draining it well and the girl made a beautiful recovery and is well to-day.

Now, I do not think there can be any doubt about the intestine having been perforated, otherwise I cannot understand why she passed blood after being shot; she later on passed fecal matter which was also thoroughly mixed with blood.

The statistics in these cases I think prove one thing—that if operations are to be done at all, they should be done promptly. And I for one profiting by my own experience in four cases, and also by a number of others that I know of here in Louisville as well as others that I have read of, am satisfied in my own mind that the best procedure is to operate upon every case of shot wound of the cavity, and I shall do so in every instance where I reach them within two or three hours after the injury. I believe that an operation done as late as ten or twelve hours after the injury gives very little promise of success, if Coley's statistics are to guide us. He was the first to make anything like complete statistics on the subject, and in his paper in 1889, he made it very clear that if you are going to operate with any hope of success you must do so early. I advocate operation in these cases, but I do believe that you must operate very early. After much fecal extravasation has taken place, and if the fecal matter has been in the cavity several hours I do

not think there is any chance of recovery.

Dr. W. C. Dugan: I had one case of gun shot wound of the bladder, which was peculiar in some respects. The man recovered without operation but I have always been of the opinion that there was simply a slit in the bladder and no extravasation of urine. The bullet was afterward removed from the bladder. Now whether it was intra- or extra-peritoneal, I am unable to say.

Dr. H. H. Grant: I would like to ask Dr. Rodman if he does not think in the last case reported by him there was perforation of the rectum behind the peritoneum.

Dr. W. L. Rodmam: I thought of that, but why should the patient have had swelling of the belly, etc.

Dr. Dugan's remarks call to mind a most interesting case I saw when I was surgeon in the Army: Dr. J. W. Bannister, Assistant Surgeon at St. Remo, Indian Ter. had operated upon an Indian scout who had been shot through the ilium, and he afterwards removed an enormous calculus from the bladder. The bullet had evidently crashed through the ilium and had either gone into the bladder or driven a splinter of bone there which acted as a nucleus for the formation of the stone. He reported the case in the *American Journal of Medical Sciences* about July, 1880, I think, and I afterward saw the patient.

Dr. Turner Anderson: Shot wounds of the bladder are not so very uncommon, where the ball lodges in the bladder. A case occurred in my practice a good many years ago. The history of the late war proves that there are numbers of cases of shot wounds of the bladder, the bullet lodging in that organ, taking all sorts of directions to get there.

Dr. J. G. Cecil: My experience in the matter of shot and stab wounds of the abdomen is very limited. I am clearly of the opinion, however, that all shot wounds where it has been demonstrated that the shot has been a penetrating one, it is safer to investigate further by a laparotomy or by enlarging the opening, than it is to leave the patient to the chances of nature. There will be very little additional shock by the operation added to that already existing, if there be any, and you clear up all doubt in the case which is a very important factor, and which if left to develop by symptoms of an inflammatory kind indicating peritonitis, sometimes renders it too late for operative procedure. I have seen several cases of the kind in the practice of other gentlemen, and have always been of the opinion that early operation was the thing to do.

As for stab wounds, my practice in this class of cases amounts to little and my opinion is merely theoretical. It seems to me however that if there is a very profound impression—and I am aware while I am saying this, that this alone is not a safe guide—that where there is a profound impression from stab wounds of the abdomen, it would be safer to investigate with view of determining if there be a wound of the intestine. We often see directly contrary statements made by men who are equally competent to judge. One man reports six cases upon which operation has been performed, in which there were five cases of gut wounds; another reports several cases of stab wounds of the abdomen and no wound of the gut. If you take these and put them together, rather if we take all cases reported here, we find that a very considerable proportion of stab wounds of the abdomen also have stab wounds of the gut. Now, when we consider that there is so little added by exploratory incision, or enlargement of the stab wound under the advanced and very thorough surgical measures, I do not think we ought to leave these cases in doubt, and certainly if I were called to see a case of stab wound of the abdomen with profound impression, whether I saw at once evidence of gut wound or not, I should be very much disposed to investigate further, believing that I would add very little to the case by making such investigation.

I was quite impressed by the remarks of Dr. Vance at the last meeting of the Medico-Chirurgical Society in regard to the method of investigating these wounds. I have been associated with him in one or two cases of this kind, in which in examining the gut large quantities were unavoidably exposed at one time. I think this is unfortunate and should be avoided if possible. There is an impression made upon the intestine by exposure to the atmospheric air and cold, and this should be avoided. If it is possible, the method that he adopted in the last case is the correct one, that is, reading the gut and

putting it back as you read, repairing it as you go along, at no time exposing more than a few inches of the gut. In this way we avoid exposure and shock to the intestine, which is a very important factor in the final recovery of the case.

DR. A. M. VANCE: I have little more to add, after thanking the gentlemen for the free discussion of this subject. I am convinced from my own observation that when a bullet perforates the bowel, that death will follow if this perforation is intra-peritoneal. If we are satisfied at the time that the missile has entered the cavity, exploration is in order. The condition of the patient generally when this point is reached, should, of course, be considered, also, the surroundings. We should always be prepared ourselves, get the best assistants possible, and get to work as quickly as we can, in the best surroundings possible in each case; do the work quickly, exposing the abdominal contents as little as the injuries will allow, and, particularly, doing as thorough cleansing with long douche tube as the condition of the patient will permit. If any time is wasted let it be in irrigation. I think we should even strain a point in favor of operation in every case, as, often, the forlornest of the forlorn cases in abdominal work will be successful. One point of importance has not been mentioned, the fact that death comes from extra-peritoneal injury which it is unsurgical to attempt to repair, as after the intestinal wounds have been attended to there is no more resistance left on the part of the patient. I mean wounds of the kidney, ureters, great vessels, &c., also the wounds of the solid viscera are often beyond repair, and cause death after the intestines are made intact.

Summary of Results in the Treatment of 701 Cases of Membranous Laryngitis by Intubation.

Dr. Dillon Brown in the *Archives* of *Pediatrics* for April states that from June, 1885 to January, 1893, he saw 701 cases of membranous laryngitis; and, with less than a dozen exceptions, they all occurred in the practice of other physicians. Those, which presented themselves in his own practice were seen by other men in consultation.

Of these cases, eighteen refused permission to operate and only one recovered; twenty-nine died of asphyxia before they could be reached; thirteen were severe septic cases with hoarseness, in none of them was the laryngeal obstruction great, and in most of them it was slight or even absent; in sixty-eight cases, although the stenosis was severe, operation was postponed with the hope that they might improve or, at least, not grow worse, one of these died during a sudden attack of dyspnœa shortly after our visit, the rest made a good recovery.

In 573 cases the obstruction grew so severe that operative interference became necessary to save the life of the patient. In all the cases, intubation of the larynx was done; in no case did the child die during the operation, although most of them were very bad and several of them were unconscious and pulseless at the time; and in no case was it found impossible to insert the tube into the larynx. These cases, of which 186 or 32.4 per cent. recovered, may be arranged in series, as follows:

Cases	1 to 100, June '85 to Aug. '87 with 22 per ct.	recov.
"	101 to 200, Aug. '87 to Oct. '88 with 32 per ct.	"
"	201 to 300, Oct. '88 to Nov, '89 with 33 per ct.	"
"	302 to 400, Nov. '89 to Apr. '91 with 29 per ct.	"
"	401 to 500, Apr. '91 to Apr. '92 with 36 per ct.	"
"	501 to 573, Apr. '92 to Jan. '93 with 45 per ct.	"

To color bone red. Boil in vinegar in which cochineal has been macerated for several days, taking care to keep every part of the article covered with the liquid. A fine deep purple red is gotten by immersing in ammoniacal carmine solution for a sufficient length of time. If a very deep color is desired, immerse the article, previously to boiling as above, in a very dilute solution of potassium hydrate for a few moments. Yellow is obtained by first immersing the article for several hours in plain vinegar or an alum solution, and afterwards in a decoction of saffron or barberry to which a small portion of alum has been added. A green stain is made by dissolving three parts of verdigris and one part salammoniac in vinegar. Blue is the result of alternate immersions in the green bath and in one of potassium hydrate. Black is the result of a bath first in a decoction of logwood and afterward in a solution of acetate of iron. These processes can be used for staining ivory.—*Cosmos.*

The Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 13TH, 1893.

EDITORIAL.

PENETRATING GUNSHOT WOUNDS OF THE ABDOMEN.

At a meeting of the Louisville Surgical Society, March 18th, the discussion of gunshot wound of the abdomen which followed showed very clearly the great revolution which abdominal surgery has made in the treatment of such cases within the last few years. It has not been very long since, that so good a surgeon as Stimpson published the statistics of the New York hospitals showing a greater mortality in those treated by section, irrigation and drainage, than in those treated expectantly. But statistics are of very little value in settling such questions because they are a barren array of figures and the modifying circumstances are left unmentioned.

It has been definitely and positively settled by a large number of cases in the hands of the best operators that the mortality depends largely upon the length of time that intervenes between the injury and the operation. Promptness in these cases adds very much to the chances of recovery. If operation is delayed for symptoms, and peritonitis has already set up section is useless. If a clean operation in skilled hands, with a short anæsthesia and a complete repair of all injuries, followed by thorough irrigation and drainage where the cavity has been handled or soiled, is resorted to, a majority of these cases will recover.

The proper way in which these cases should be handled is beautifully shown in the report of the case, in this issue of the REPORTER by that brilliant surgeon, Dr. A. M. Vance, of Louisville; though, in sewing up the wounds of the bowels we would prefer silk to catgut.

When the surgeon is called to see a case of gunshot wound of the abdomen the first thing to be ascertained is whether the abdominal cavity has been penetrated. The quickest, easiest and safest way to settle this question is by exploratory section. Let the surgeon waste no time in amusing himself with such surgical toys as the hydrogen gas test. If he does he will begin in doubt and probably end in disaster. A clean knife, in clean hands, with surroundings as clean as soap and boiled

water can make the m will give him more information and in a safer manner than he can gain by dallying with refinements of surgical invention. It is not necessary that a man should be carried to a hospital to be successfully treated. The genius of a surgeon is no where more clearly or beautifully manifested than where he compells surroundings to suit himself. Some of the most beautiful and successful work ever done in Philadelphia, or for that matter in the world, was done at the homes of the patients where all that was necessary to success was carried in the operating bag of the surgeon and beneath his hat. Success in these grave emergencies depends more upon the man that does the work than it does upon the place where it is done. The successful surgeon is independent of hospitals. With him a hospital means simply a patient, a good nurse, an operator and a room. It matters not whether this room is in a building with one hundred other rooms or in a building with only one other room, he adapts means to ends and with him there is no such thing as fate.

Give such a man a patient shot in the abdomen, and with a short incision, rapid work, plenty of water, short anæsthesia, quick repair of injuries and as little exposure of viscera as possible, clean hands, instruments, field of operation and dressings with a proper regulation of diet and a withholding of opium and we will have the lowest mortality possible and a showing that will send expectancy into innocuous desuetude.

TRANSLATIONS.

TREATMENT OF CERVICAL STENOSIS BY BILATERAL DISCISSION.†

In (*Le Bull. Med.*, February 22, 1893), Pichevin says, that in a recent work read before the *Soc. de Chirurg.*, Pozzi made an attempt to revive the favorite operation of Sims—"The gynecological operation par excellence"—bilateral incision of the neck of the uterus for the purpose of correcting stenosis of the external orifice and congenital narrowing of the cervical canal. Discission of the neck was practised for the first time in 1873 by Simpson. Sims used and abused this operation. With it he treated dysmenorrhœa and proposed to do away with sterility, dependent upon deformity of the cervico-uterine canal.

In reading over the clinical notes upon uterine surgery it may be noticed that the celebrated American gynecologist was not mistaken in recognizing the true value of bilateral section, and that he had very precise opinions upon the indications and contra-indications of this operation.

Sims had noticed that after sections of the neck, according to his process, the two lips of the incisions made laterally showed a tendency to reunite. The cervical cavity did not delay in closing and at times the external orifice was as contracted after as before intervention. The operation did not tend therefore to a permanent result. Pozzi thought that it was sufficient to prevent reunion of the two cervical lips in order to obtain a more durable result than that which had been obtained by the great protagonist of bilateral discission. He modifies the operation as follows: He carries each of his incisions high up on either side. He thus has two long cervical lips—the one above—the other below. On drawing the upper valve upwards and the lower downwards there is brought before the eyes a large part of the cervical cavity. The cervical mucosa is divided into two portions corresponding to the two lips. If now the inner aspect of the upper lip is examined, upon the median line may be noticed half of the cervical

†Translated for THE MEDICAL AND SURGICAL REPORTER, by W. A. N. Dorland, M. D.

mucosa and laterally two raw surfaces resulting from the section of the cervical parenchyma. Upon this raw surface, contracted transversely and elongated from before backwards, Pozzi forms a long flap in the shape of a wedge. A longitudinal incision starts from the angle of separation of the two lips and descends through the length of the cervical mucosa upon the bleeding surface up to the anterior extremity of the neck, that is to say, as far as the divided external orifice.

A second incision is made upon the same surface of the lateral section through the length of the vaginal mucosa of the neck. The incision commences at the angle of separation of the two lips and terminates at the external orifice. Two parallel incisions are carried through the thickness of the uterine tissue until they meet. There is thus formed a long flap of a prismatic and triangular form. One of the faces of the prism looks forward and includes the greatest portion of the bleeding surface. The angle is found in the depth of the cervical parenchyma. When the flap is lifted up the surface of the lateral section is converted into a sort of gutter, the base of which, in place of being rounded, is flattened laterally. The internal border of the gutter corresponds to the cervical mucosa; it is the cervical flap; the external border is parallel to the vaginal mucosa which is reflected upon the cervix—this is the vaginal flap. The sutures are passed transversely in such a way as to approximate the vaginal to the cervical flap, from the angle of separation of the two lips up to that portion of the section which corresponds to the external orifice. Thanks to these sutures the approximation is perfect. The lateral bleeding surface no longer exists. The same manœuvres are repeated upon the other lateral section of the anterior lip. The lower lip is treated in the same way on the right and on the left. The result is the following: The bleeding surfaces on the lateral halves of the divided neck are covered in. The right lateral section of the upper lip cannot be reunited to the right lateral section of the lower lip. The left lateral section of the upper lip cannot adapt itself to the corresponding section of the lower lip. There is thus avoided a reunion of the two cervical lips. The neck remains divided to a considerable height.

The primary and separate union of the four surfaces of the lateral sections prevents the danger of infection which might appear after the operation if the bleeding surfaces are not sutured together. There is thus avoided the formation of all unhealthy tissue, and of cicatrices if the operation has been performed in accordance with the rules of antisepsis. The originality of this proceeding consists therefore in the freshening of the bleeding surfaces and in the separate reunion of the borders of each valve.

Pichevin concludes that there are some important objections to this operation. It has already been said that the cervix after the operation was a bi-lacerated cervix and consequently worthy of treatment by a double Emmet operation. Pozzi replies that it is not necessary to compare a cervix divided surgically and treated as he indicates with one torn pathologically.

In the first case the reunion is by first intention and there is no production of granulation tissue. When the cervix is torn in labor it becomes the seat of more or less marked inflammation and cicatricial tissue is formed, especially in the angle of reunion. Emmet's operation is not especially directed to the deformity of the neck, it consists essentially in the removal of the granulation tissue and reunion of the freshened surfaces.

Secondly: It may be asked, as has been suggested by Spencer Wells and Sims, whether bilateral incision does not cause eversion of the lips of the cervix. Both have observed this complication after high discission of the cervix. This ectropion is not produced by contraction of the longitudinal fibres after section of the circular fibres. Another element of capital importance should be taken into consideration—viz.: infection of the cervical mucosa.

Thirdly: A bi-lacerated cervix divided into two clearly separated lips is no longer a physiological cervix. The form is destroyed and the functions, if not profoundly altered, at least and strongly comprised.

Fourthly: There is no longer a cervical cavity. It is replaced by two grooves widely separated, true diverticuli of the vaginal canal. The cervical mucosa in direct communication with the vaginal mucosa is exposed to all the causes of vaginal infection. Thus total discission

of the intra-vaginal portion places the cervix in imminent danger of disease.

Pichevin concludes that bilateral division of the cervix performed according to Pozzi's method is indicated only in exceptional cases.

ACUTE FORMS OF GASTRIC HYPERASTHEMIA.†

According to Robin (*Le Bull. Med.*, Feb. 26, '93), the chemical study of dyspepsia, and its classification based upon analyses of the gastric juice, is of recent date. It was Leube, who in 1875, first investigated the subject. He observed in certain cases, the diminution or the defect in the hydrochloric acid in the stomach. In 1882, and then in 1884, Reichmann published his observations of two patients in whom dyspepsia was due to the presence of an excess of hydrochloric acid in the stomach. In 1884, Rossbach described gastroxynsis, which is an exaggerated secretion of hydrochloric acid, occuring not continuously as in Reichmann's disease, but in paroxysms. Since then other investigators, among them Von der Velden, Gluzinsky, and Jaworsky in Germany, G Sée and his pupils, Hayem and Winter in France, have studied the subject.

Hyperhydrochloria has no characteristic etiological, chemical, or clinical feature It may be due to a nervous trouble which may give rise to a dyspepsia without excess of hydrochloric acid, or it may be the expression of a purely local trouble of the stomach with secondary reaction upon the nervous system. Chemically, it has no characteristic feature. Hayem has noted a case where notwithstanding excess of chlorides there was not an excess of free hydrochloric acid. This condition he would call *hyperpepsia.* Again, "the hyperacidity may be due to an excess of lactic acid, or to the presence of both lactic and hydrochloric acids. This will overthrow the opinion that hydrochloric acid is an antiseptic preventing abnormal fermentation, particularly lactic acid fermentation. Finally, hyper-hydrochloria has no clinical characteristic. It is true that there exists a morbid type characterized clearly by hyper-hydrochloria, but frequently, if not always, this is associated with troubles of the muscular contractility of the stomach. Vonloir describes on the one hand a hyper-hydrochloria dyspepsia, and on the other hand a motor dyspepsia, that is separating artificially diseases eftenninseparable in reality. Hyper-hydrochloria is therefore a chemical state, a symptom, if you wish, but cannot designate a disease as the word fever, or the word cough for example.

Hypersthenia may be acute or chronic. The acute variety may present itself in three forms, as follows:

1. Acute paroxysmal hypersthenia of nervous origin.
2. Acute intermittent hypersthenia of central origin.
3. Acute intermittent hypersthenia of direct origin, that is to say stomachic or reflex.

Acute paroxysmal gastric hypersthenia of nervous origin, Rossbach's disease called by the latter gastroxynsis, a name transformed by Lépine into *gastroxia,* is the hyperacid vomiting of Rosenthal. It consists in paroxysmal association of too painful phenomena, cephalgia, and gastralgia accompanied by very acid vomiting. The crises occur at intervals more or less widely separated and are under the influence of a central neurosis. It is a much more frequent affection than is generally suffered. It is generally confounded with migraine. In the latter, however, the cephalgia predominates, while in the former the gastric state is most prominent. Then prophylatic treatment, while ineffectual in the case of migraine, is very efficacious in hyper-hydrochloria. The suppression of all intellectual work, and a sea-voyage, or sojourn in the country will suffice to cure the condition.

Acute intermittent gastric hypersthenia of central origin, that is to say, secondary to an affection of the nerve centers, is best seen in the gastric crisis of ataxia. It may be encountered in general paralysis, multilocular sclerosis, or in hysteria. It is of great importance to distinguish it, as it will help to reveal a grave affection of

† Translated for The Medical and Surgical Reporter, by W. A. N. Dorland, M.D.

the nerve centers the existence of which had as yet been unrecognized. Sahli was the first to notice hyper-hydrochloria in the gastric crises of ataxia. Bouveret and Boas recognized the condition after him.

Intermittent gastric hypersthenia of direct origin (*stomachic or reflex*) originally in the stomach. There are two varieties, the one stomachal or alimentary, the other reflex or periodic. The former is a simple variety, since all that is necessary to meet the condition is a hygienic regulation of alimentation to avoid a return of the condition. In the reflex or periodic variety the conditions are otherwise. The origin of this form may be in the aorta, heart, uterus, or liver. It is characterized by anorexia during the crisis. The vomitings are frequently over acid, and constipation is the rule. An important symptom is acceleration of the pulse at the height of the crisis. Another characteristic is the abrupt onset and cessation of the attack. Robin in the treatment of this variety orders the following:

℞ Magnes calcinel..... o gr. 60
Coarse powdered opium .... o gr. 02
Bismuth subnitrate ..... o gr. 30
After each meal in a cachet.

The prophylactic treatment consists in the treatment of the diseased organ.

ABSTRACTS.

SLEEP AND ITS DISTURBANCES IN CHILDREN.

Of all the attributes of human beings, sleep is the one that dominates them most tyranically. Its deprivation is the cause of the greatest suffering, its presence is nature's most precious gift. During activity of the body and mind it is that the most destructive changes go on in the body, and during repose and rest that such changes are repaired, and so it follows that just in proportion as is the tearing down so must be the building up.

IMPORTANCE OF PERIODICAL REST.

The necessity for sleep varies in different nations, in different people, in different ages and in various other ways. The amount of sleep necessary for an infant is more than double that required for an adult, and this is accounted for by the purely vegetative existence a child lives during the first few months of its life. As it grows older and the ability to acquire ideas is given to it, the necessity for sleep is less manifest. For instance, a new-born babe should sleep continually while it is not feeding, while at one year of age fourteen hours of sleep are quite sufficient.

Although disturbances of sleep are of not so frequent occurrence in infancy as at a later period, their advent at this age is one of the most serious drawbacks to the preservation of health. As a general rule, it may be said that a child who sleeps well, eats well, and thrives vigorously, is able to resist the occurrence and inroads of disease; while, on the other hand, the child who sleeps insufficiently is apt to be peevish, irritable and nervous during the day, and its health become seriously disturbed as the consequence. Such children are easy victims of current diseases.

WHAT CAUSES SLEEP?

For a long time it was thought that sleep resulted because there was an excess of blood in the brain, a blocking up and sluggishness of the circulation as it were; but this idea was long ago exploded, and now all physiologists agree that the underlying factor in the occurrence of sleep is a diminished amount of blood sent to the brain under a diminished amount of pressure. This has been proven in many ways.

The special senses are of the highest development and organization, and it is here, by the cessation of their function, that the diminution in the quantity of blood is first made manifest. For instance, we know that one of the easiest and most certain ways of inducing a state of drowsiness is by tiring some one of these special senses, such as sight and hearing. A practical manifestation of this is seen every day in the nursery where the singing of a lullaby quickly im-

presses the hearing of the babe, and sleep is the result. It is seen in another way in sleep that is induced by the ill-advised habit, more in vogue formerly than at present, of rocking. Those who have sat by a cradle and watched an infant from the time it is first put in until it is asleep have noticed that at first it lies with its eyes wide open, and, while it rolls from one side to the other with each swing of the cradle, its eyes travel over a large area, but do not dwell on any one spot sufficiently long to have its little mind impressed; in this way its brain becomes fatigued with a good deal of rapidity, and sleep rapidly follows.

One is often surprised to see the rapidity with which young children drop off into sound sleep, but it is a simple exemplification of their weak powers of attention, and anything which diminishes this attention induces sleep. After the mind has been strained or excited in one particular direction and the reaction follows, sleep comes on very quickly.

AIDS TO SLEEP.

Knowing, then, that this condition of the circulation is the *sine qua non* of sleep, means should be taken to facilitate its occurrence and to remove any obstacles that might hinder it. In this way attention should be given to the temperature of the sleeping room, the position of the head, the amount of pillow and covering, and the position the child should occupy. It is unnecessary to say that the night dress about the neck should be sufficiently loose, so as not to offer the slightest degree of constriction, and it should be made of flannel or silk. The pillows should not be too soft, and of only a moderate height. A slight elevation of the head contributes to bring about the desired condition as regards the circulation in the brain; while, on the other hand, if the head be too high, the heart must work harder to pump the blood in, and therefore it will enter with a greater degree of force—an undesirable result.

Regarding covering, it is here that mothers err most often. It is no uncommon occurrence to have a child put to bed with no more covering in the night than it had in the shape of clothing during the day. Yet during the night the window is probably open, the temperature of the body has dropped from $\frac{1}{2}$ to one degree, and the vital functions are all at a lower ebb than they were during the day. Of course, combustion is at the bottom of all heat production, and in the human body it is the combustion of the food stuffs with the oxygen that is taken in at every respiration which results in the formation of animal heat. The process of combustion goes on mostly in the blood; and as the circulation of the blood is slowed in sleep, as has already been pointed out, it will be readily seen that less heat is manufactured during the night than during the day; and it follows that greater precautions should be taken for the conservation of the bodily heat during the former than during the latter. As a matter of fact, however, this is often neglected. It matters very little what the temperature of a sleeping apartment is, so long as it is not above 55 degrees, and providing that when it is cooler the cold air is prevented from coming in too direct contact with the child's body, and thus causing too rapid radiation of heat.

Of course, there is such a thing as putting on too much covering at night, but the danger is more apt to be that there is too little than too much. An excess of clothing has a tendency to increase the calibre of the blood-vessels, and, therefore, to allow of a larger accumulation of blood in any of the organs, and particularly those more directly in contact with the pillow and the bed, viz., the head and spinal cord. This, therefore, should be looked after.

A moderate degree of warmth predisposes to continual and undisturbed slumber. A child put to bed in a moderately cool room and with sufficient covering to keep it comfortable while the temperature of the room remains the same, will sleep on undisturbed. Toward morning, however, when the mercury falls considerably, the cold air will stimulate a greater activity of the heart and respiration in order to obtain the necessary elements for the manufacture of bodily heat, and the results are that more blood is sent to the brain, and the child awakes. This is a conservative process on the part of Nature to prevent us from taking cold. If the stimulus is not of sufficient intensity to cause complete awakening, it will result in sufficient blood being sent to the brain to call some of its functions of intelligence into activity, and the results are

dreams, denoting imperfect slumber and restlessness. It is not at all necessary that the entire surface of the body should be exposed to the cold in order that these influences may be transmitted to the brain; frequently it results from cold hands and feet alone, and occasionally from other forms of irritation. Intense heat will do the same thing, and such is the cause of early wakefulness in summer when the thermometer indicates a high degree even in the early morning.

As regards the position of the body most conducive to normal slumber, it may be said that young children sleep best when on their back, but as they grow older they should be accustomed to sleeping on the right side. The right side is to be preferred to the left on account of the heart and stomach being on the latter side, and pressure on either one is not always borne without remonstrance.

Too much care cannot be expended in getting perfect ventilation for children's bedrooms. Such perfect renovation and restoration of the tired and wasted parts goes on during sleep that it is a pity to hamper this beneficent influence by stinting the amount of fresh air. When the ventilation is perfeet the child awakens chirping and bright, and is full of activity and life, for the reason that during the night all the waste products of the system, the result of the previous days activity, have been eliminated from the system. If, on the other hand, the access of fresh air has been imperfect, the child arises peevish and unrefreshed, and a continuous recurrence of this will soon result in manifestations of ill health.

COMMON DISTURBANCES OF SLEEP.

The most common disturbances of sleep in infancy are night terrors, insomnia, nightmare, dreams and sleep-walking or, as it is technically called, somnambulism; and of these the most painful and distressing to witness is the first named. Insomnia, which in later life becomes so troublesome is comparatively rare in infancy. Children who suffer from night terrors are generally weakly and delicate, and frequently of nervous parents. They are rarely strong and robust and often are troubled with some disorder of digestion, although sometimes this disturbance occurs in children who are generally otherwise quite well.

The attacks ordinarily come on in a very abrupt manner. The child has been put to bed apparently well, and after sleeping from one-half to two hours, suddenly starts up with a most terrifying shriek, accompanied by gestures indicating that he sees something which is repulsive and is frightening him. The eyes may be wide open and staring; he calls loudly for his mamma or nurse, but when they approach he does not recognize them, and perhaps struggles to get away from them. Soon a profuse perspiration appears, and after a variable time, lasting from a few minutes to an hour, he begins to recognize his surroundings, and frequently, without becoming thoroughly awakened, he nestles up in his mother's arms and sinks into a peaceful slumber like the one from which he was aroused. Sometimes, when thoroughly awakened, he can give no idea of what frightened him, and, if old enough to talk, seems to be somewhat reticent about mentioning it; then after passing a large quantity of urine he quickly goes to sleep. Often these children while in attack will make gestures as if warding off some repulsive or dangerous object, and, again, will cower in the corner or under the bed as if endeavoring to escape some imaginary foe. Frequently when the mother or nurse attempts to soothe them they will continue to struggle in efforts to escape. These attacks recur at varying intervals, frequently not more than once a week, and it is very rare for a child to have more than one attack in the same night.

When we attempt to trace a direct connection between the attack and some immediate cause we often find that it is impossible. Occasionally the child may have had a fright, or has been punished, or has gone to bed with an over-filled stomach, but ordinarily none of these factors will be present. Teething has been thought to be a cause, but these attacks are most apt to occur between the ages of two and six years of age, a period when the first teeth have already appeared and the second are not due. In some instances there is no doubt but that the appearance of an attack may be due to the most barbaric custom of telling blood-curdling ghost stories, and particularly from a nurse filling the mind of a child with the idea that goblins are standing ready at the gates to carry it away and

subject it to the most inconceivable sorts of punishment if it does not go to sleep right away; as a consequence such children are frightened into sleep, but the impression made by the threat is still rankling in their unconscious thoughts and it starts a mutiny in the otherwise well-regulated brain. Ghost stories are most pernicious at their best, and even when told to adults; but when told to nervous, irritable and easily excitable children, it is little less than manslaughter. The degree of suffering which such children endure when left alone or placed in a dark room is hardly conceivable.

Fortunately, the occurrences do not lead to any more serious disorder and are quite amenable to ordinary domestic treatment. It is unnecessary to state that the cause for an attack should be sedulously looked for, and, when found, removed at once. Such children should have a very light supper, from which meats must be absolutely excluded and likewise sweetmeats, for there can be but little doubt that these are often potent factors in causing an attack. If the child has been noticed to breathe through the mouth while sleeping, or if he snores, his tonsils should be examined, and treated if enlarged, or if he has symptoms of catarrh. In the same manner constipation, if it exists, should be overcome by the administration of a teaspoonful of rhubarb and soda mixture when the child goes to bed. If during or before an attack the child wets the bed, the nurse should be instructed to awaken him on the following nights and take him out in anticipation. Such a child should be given a cold sponge bath every morning the year through, followed by a thorough rubbing down with a crash towel until the skin is of a scarlet red all over; he should then be warmly but lightly clad and encouraged to get moderately tired by playing in the open air. If he has a tendency to take cold easily, this is the best indication that he is not assimilating sufficient fatty foods, and small doses of cod liver oil should be given after each meal.

It has often been suggested that these children when they have an attack of night terrors be dipped into cold water to cause their terrors to end; but this cannot be recommended. They should, on the contrary, be soothed in every way possible, and an endeavor made to call into activity the higher parts of the brain, and so get completely aroused.

It is needless to say that, if the attacks are due to any condition of depraved health, such will need scrupulous attention from a physician; but attention to the diet and the hygiene of the sleeping apartment will prevent the recurrence in a large proportion of the cases. From the fact, as already stated, that these attacks are more apt to occur in patients who are nervous and irritable, measures should be taken to discipline their minds at the same time with their bodies, and so restore the stability necessary to both.—*The Mother's Nursery Guide.*

Amusing Ingratitude.

It is often said that physicians are well used to ingratitude, but perhaps they could bear the unpalatible draught with composure if it were always as amusingly presented as in the following case:

Dr. J. M. Warren had been in the habit for a number of years of giving professional advice to a lady in reduced circumstances, whom he regarded as hardly able to offer him any compensation.

At length she ceased consulting him and he did not see her for a long time. Finally, happening to meet her in the street, he said to her:

"Why, Mrs.——, what has become of you? You haven't been near me for months."

"Well, the fact is, Dr. Warren," she said with all simplicity, "I didn't seem to gain very much and I thought I'd consult a paydoctor."

Hysterical Female.

We blistered her back; at her rectum we whacked,
'Thout finding the lesion that ailed her;
We rubbed down her spine till the skin it did shine,
And all our kind service but failed her.

With pill and with powder we often did crowd her,
But she cried the louder: "Give something more strong!"
We doubled our blisters, gave capsicum clysters,
'Twas always this: "Misters, you're all in the wrong.

"Can't you use your big spectrum and look at my rectum?
You can cure me if ever you try;
Or give an injection after my own direction,
If you don't I will certainly die?"

—*Daniel's Med. Jour.*

CURRENT LITERATURE REVIEWED.

THE AMERICAN GYNECOLOGICAL JOURNAL

For February. Dr. H. W. Longyear contributes a paper on

Peritonitis,

reporting two cases: the one treated by the old method of opium with the result of the masking of all symptoms and death on the third day, the post-mortem showing purulent peritonitis due to the rupture of a small ovarian abscess; the second case, presenting analogous symptoms, recovered promptly under modern surgical treatment. Taking these two cases as his text, the author reviews the causes of peritonitis and the results of the treatment by opium and those obtained by the opposite course of free purgation and the resort to surgical measures where necessary. He unhesitatingly advocates the latter, fully endorsing Dr. Joseph Price's dictum that "Opium has no place in the treatment of peritonitis." "The order of the day," he says, "is now purgation, causing activity in all secretions and acceleration in of the process of osmosis, resulting in the rapid elimination of the natural waste of the body, as well as of foreign septic material. The old order, that of opium, meant stagnation and locking up of secretions, thus favoring the retention of the waste and effete products of the system and the absorption of septic material." He urges on the practitioner the importance, in justice to his patient, of early counsel in every case of peritonitis. "By 'early' is meant *as soon as diagnosis is made*, and not after three or four days of experimental treatment have passed. All cases do not demand operation, but many that do, demand it early, and the golden opportunity may be lost in waiting. By 'counsel' is not meant another general practitioner, who perhaps never does surgery, and consequently can form no opinion of the surgical needs of the patient, and who is expected to see the patient but once and then do little more than to agree with all that has been done. The consultant should be selected with as much regard to the anatomical part affected as is the case in serious affections of the eye and ear, when the oculist is called. In disease of the peritoneum the need is for a man of experience in abdominal and pelvic surgery, who, by the almost daily handling of the peritoneum covered viscera of the body, is so accustomed to noting the behavior of these parts under different forms of irritation that his advice will be of practical value. He should also see the patient often with the attending physician until the critical stage of the disease has passed. By such an association of experienced counsel not only will the best interest of the patient be considered, but there will result an advantage to the attending physician, thus dividing the great responsibility that always attends this dangerous disease."

Dr. Frank A. Glascow discusses the

Treatment of Endometritis,

describing a new advice for draining the cavity of the uterus. The drain is made of a number of strands of silk worm gut the ends of which are tied together in a knot, thus forming a loop. When this is introduced above the os internum, the largest part of the loop being uppermost, it would have very little tendency to come out. The knot and ends are covered with a thin strip of guttapercha. He has used this drain for about two years and has never yet seen any bad result from its use. He would advise that the drain be kept constantly in a strong carbolic solution and that the cervix be thoroughly cleaned before introduction.

Dr. Ely Van De Warker considers the subject of

The Treatment of Chronic Pelvic Pain.

He condemns the removal of ovaries for simple pain and makes the assertion that there are many cases of pelvic pain for the relief of which it is not proper to remove the uterine appendages; and further that there are many cases of pelvic pain in which these organs are perfectly healthy, and the conclusion is logical that their extirpation could furnish no relief. He also condemns the routine use of morphia for the relief of pain, using in its place codeia, which, however, he reserves for what he terms severe pain. He states that it is not open to the same objections as morphia. He speaks in high praise of viburnum, especially in combination with pulsatilla. Aletris farinosa is another of the milder pelvic sedatives which has a good general reputation but from his experience he doubts if it can be relied on to overcome a painful state of any of the pelvic organs. It serves a more useful purpose when given in combination. Belladonna is a very powerful pelvic sedative but must be used with caution. The sitz bath and the hot douche are valuable agents when properly employed. He also advocates the use of what he terms the combined douche. "With the patient lying, she is given a vaginal irrigation of about fifteen minutes with water at the 110°. This current is shut off and one of 70° substituted. The theory of its use is to produce a marked shock upon the arterial circulation of the congested organs. If a contrast of 40° is too great it may be lessened by giving the initial douche at 95° to 100°." "As a method of controlling painful pelvic conditions the effect of properly adjusted manipulation of the parts within the pelvis must be overlooked. This is sometimes called massage, but if by that term is meant any of the indescribable manipulations known as Brandt's method the term is misapplied." Two objects must be in view; first to break up, or to cause the absorption of adhesions between the intrapelvic parts. Secondly, to relieve the venous engorgement that results from want of exercise or the immobility caused by adhesions. Tampons of lamb's wool he

has often found of benefit where it is desirable to diminish the blood supply in the lower uterine segment. The use of the bromides is emphatically condemned. He concludes with the advice not to treat tubal disease with any of the methods detailed in the paper. As a rule, a tube filled with pus or any other fluid accumulation, has but one remedy, and that is its removal by laparotory. It ought to be removed early before the health is broken down. Especially is electricity not to be employed in any form of distended tube with the idea of curing it.

Dr. J. C. Sexton reports a case of

Moya Complicating Pregnancy.

The patient was delivered of a child at the sixth month. The third stages of labor being accompanied with a very severe post partum hemorrhage. Three months later the tumor was removed by supra vaginal hysterectomy. The symptoms and prognosis of these complications are considered as is also the differential diagnosis.

Dr. Charles N. Smith contributes a paper on "The Natural History of Gall-stones," discussing the various theories as to their formation and also the symptoms and diagnosis of the affection.

THE CANADIAN PRACTITIONER

For April. Dr. W. B. Thistle contributes a paper on

The Eliminative and Antiseptic Treatment of Typhoid.

If it be conceded that typhoid fever is the result of the location and growth in the body of a specific form of bacterium, the question is, can we by any form of treatment get rid of any portion of the poison already formed; prevent, to any extent, the production of further poison; limit, to any degree, the action of the poison already in contact with the tissues? The author is of the opinion that by the adoption of a plan of treatment which combines free elimination with antisepsis these several results will be obtained. His plan of treatment is to combine the use of purgatives with some one of the various antiseptics—salol, thymol, naphtol, sallcylate of bismuth, etc. In his practice he has employed calomel for the purgative (though he believes the salines would answer as well) and salol for the antiseptic. The patient is also given plenty of water in order that the poison may be eliminated by the kidneys. He believes this treatment not to be dangerous to the patient and reports a number of cases to prove his theories. He holds that purgation does not increase the risks of perforation of the intestines but rather diminishes that risk. Under the treatment patients rapidly improved and the disease seemed to assume a milder form.

L. M. Sweetnam, M. B., discusses

The Treatment of Varicose Veins of the Lower Extremities.

The causes, symptoms and various forms of this disease are thoroughly entered into. The operative treatment by the ligature and by excision receive especial attention. The author urges excision as the best procedure in well-selected cases calling for so called radical treatment.

Dr. Hunter Robb contributes an abstract of Prof. Gusserow's article in *Arch. fur Gynecologic*, on "Ascites in Connection with Gynecology."

A. McPhedran, M. B., reports a "Tubercular Cyst of the Peritoneum, Simulating Hydatid Cyst of the Liver."

SELECTED FORMULÆ.

In cases saturated with the approved remedies, but still presenting patches on the skin and mucous membranes.

℞ Acidi nitro-muriatici diluti..... ʒij
Sprupi stillingiae compositi ..... ʒxiij ss
Aquae destillatae..... ..... ʒij
M. Sig. Dose, one to two teaspoonfuls three times a day, with denutrition.

—*Bartholow.*

Paralysis.

In the dihptheritic paralysis; in local paralysis, such as facial, of the vocal cords, in lead palsy, paralysis of the sphincters ani and vesicæ; also in paraplegia when no structural alteration of cord, and in long-standing cases of hemiplegia, Bartholow uses:

℞ Strychninae sulphatis..... gr. j
Aquae destillatae ..... ʒx
Fiat solutio..... .....
Sig. For hypodermic use. Ten minims contain 1-60 gr. of Strychnia sulphate. Inject in substance of paralyzed muscle.

Pleurisy.

In chronic pleurisy with consolidation of lung Prof. Da Costa orders:

℞ Potassii iodidi..... ..... ʒij
Tincturae scillae ..... ʒvj
Tincturae opii camphoratae..... ʒiss
Misturae acaciae .. .. ʒvj
M. Sig. A teaspoonful four times a day.

Or in dry pleurisy,

℞ Morphinae acetatis..... ..... gr. ss
Potassii acetatis..... ʒss
Tincturae veratri viridis mx..... xxiv
Syrupi talutani..... ʒss
Liquoris potassii citratis..... ʒij ss
M. Sig. Two fluid drachms every three hours.

Lumbago.

Instantaneous remedy:

℞ Collodion.....
Tincturae iodi .....
Lig. ammon. (equal parts of each)..
Apply freely over the parts affected with a camel's hair brush and instantaneous relief will be afforded.

—*Ex.*

Otorrhœa.

Antiseptic wash in the treatment of otorrhœa.

℞ Hydrar bichlor..... gr. ss
Acid tartaric..... gr. xx
Aquae, q. s. ad..... ℥xj

M. Sig. Wash out the ear first with warm water then fill the ear with the above solution.

—*Amer. Jour. M. Sc.*

Carbuncle.

The following, says Buxton Shillitoe, will sometimes abort a carbuncle or boil if applied early.

℞ Extract opii..... ℥ss
Glycerinae, q. s. nt. fiat. magma..

M. Sig. Smear thickly over the swelling three or four times a day; then apply

℞ Pulveris opii.....
Ungnenti hydrargyri.....
Saphonis durae āā..... ℥ss

M. Sig. Apply spread on think leather.

Rheumatism, Chronic.

℞ Pulveris guaiaci resinae.....
Potassii iodidi āā..... gr. x
Tincturae colchici seminis..... ℥ss
Aquae cinnamomi.....
Syrupi simplicis, āā q. s. ad..... ℥j

M. Sig. A desertspoonful to a tablespoonful thrice daily.

—*Philadelphia Hospital.*

Dr. Gerhard recommends as quite an efficient liniment the following.

℞ Chloroformi.....
Tincturae aconiti radicis.....
Alei terebinthinae, āā..... ℥ ss
Alei sassafras..... m. v.
Linimenti saponis camphorati..... ℥ij ss

M. Fiat linimentum.....

Cutaneous Diseases.

Nothing is better says A. T. Thomson, to alloy itching in cutaneous diseases than

℞ Plumbi acetatis..... gr. xvj
Acidi hydrocyonici diluti..... ℥iss
Spiritus rectificati..... ℥ij
Aquae destillatae..... ℥vii ss

M. Fiat lotio.

Seatworms.

℞ Hydrargyri chloridi mitis..... ℈iv
Ungnenti petrolei..... ℥vj

Sig. Amount anns and vulva.

—*Valleix.*

Cholera Infantum.

For a child one year old.

℞ Argenti nitratis..... gr. i
Acidi nitrici diluti..... mx
Tinct. opii deodoratae..... mx viij
Mucilaginis acaciae..... ℥ss
Syrupi simplicis..... ℥ss
Aquae menthae pip..... ℥i

M. Sig. One teaspoonful every three, four or six hours.

—*W. H. Bricker.*

Syphilis.

℞ Hydrargyri biniodidi.....
Potassii iodidi.....
Aquae destillatae.....
Syrupi simplici.....

M. Sig. A tablespoonful thrice daily.

—*Hospital Saint Louis.*

Neuralgia.

℞ Strychninae sulphatis..... gr. j
Morphinae sulphatis.....
Acidi arseniosi āā..... gr. iss
Extracti aconiti..... gr. xv
Quininae sulphatis..... ℥i
Misce et. fiant pilulae No..... xxx

Sig. Take one pill three times a day.

—*S. D. Gross.*

Earache.

The following rarely fails to give prompt relief:

℞ Tincture aconite radicis..... ℥iss
Glycerini..... ℥ii ss

M. Sig. To be warmed and dropped into the ear.

—*Gerhard.*

For Excessive Thirst in Diabetes.

℞ Pilocarpinae nitratis..... gr. iii
Spiritus tenuioris..... ℥i
Aquae ad..... ℥ss

Sig. Four or five drops on the tongue twice or thrice daily.

—*The Practitioner.*

Chloral in the Treatment of Boils.

M. Sphen recommends very highly, as far superior to all other treatment, the use of chloral externally in this troublesome class of affections. He directs that the boil be kept covered with a tampon of cotton-wool soaked in the following solution:

℞ Chloral hydrat..... ℥ iiss
Aquae.....
Glycerin āā..... f ℥ v

Misce.

—*Bull. Gen. de Therap.*

Chilblains.

℞ Carbolic acid (white)..... 1 drachm
Tannic acid..... 1 drachm
Tincture of iodine..... 2 drachms
Vaselin (albolene)..... 4 ounces.

M. Sig. Apply to the affected part three or four times a day.

—*Doctor.*

An Agreeable Salicylic Mixture

℞ Potassii acetatis..... ℥ii
Acidi salicylici..... ℥ss
Syrupi limonis..... ℥ii
Aquae menthae piperitae ad..... ℥viii

Sig. One tablespoonful every three hours.

—*The Practitioner.*

Swollen Eyes.

If the eyes are swollen, use on them:

℞ Acid boracic..... 12 grains
Aquae camphorae..... 2 ounces
Aquae Dest..... 2 ounces

M. Sig. Bathe and drop in the eyes frequently.

—*Ex.*

For Chronic Eczema.

℞ Acidi salicylici..... gr. xxx
Zinci oxidi..... ℥vi
Pulveris amyli..... ℥vi
Vaselini..... ℥iss

Sig. The paste to be applied daily, not to be washed or rubbed off.

—*Ex.*

PERISCOPE.

THERAPEUTICS.

The Influence of Massage upon the Rapidity of the Absorption of Therapeutic Substances.

The author has observed the rapidity of the absorption of toxic substances in dogs under the influence of massage. and has obtained the following results, which we analyze briefly:

1. Massage made in the direction of the heart accelerates the absorption of the liquid substances introduced beneath the skin.
2. It augments considerably the effect of these substances. From a therapeutic standpoint this fact is of great importance, as a small dose of a medicament associated with massage may yield the same results as a larger dose without massage.
3. The longer the massage is continued the more rapidly are the effects manifested.
4. The quantity of the injected fluid has no marked influence upon the rapidity of the absorption during the massage.
5. Massage of the corresponding portion of the opposite side of the body has no influence upon the rapidity of the absorption.
6. Massage produces a dilatation of the blood vessels of the organ to which is is applied.
7. When the sciatic nerve is divided, the liquid which is injected below the point of the section is absorbed with greater rapidity.

The influence of massage upon absorption is not due to the production of vascular constriction or dilatation owing to the irritation of the peripheral nerves. The dilatation is produced mechanically, and the blood of the region being forced into the general circulation, more rapid absorption results.—*Therapeutic Review.*

MEDICINE.

Paraldehyde.

Mackie in the *British Medical Journal* refers to a series of cases of asthma in which paraldehyde stopped the spasm and produced sleep. Some of the cases were of long standing. Thirty minims were given every hour or half hour until relief came. Three doses were generally sufficient. In children a smaller dose should be given.—*Brooklyn Med. Jour.*

Cautionary Facts.

1. Drugs by the rectum or vagina should be given in *three* (3) times the dose by the mouth.
2. Drugs by the hypodermic method should be given in *one-sixth* (1-6th) the dose by the mouth.
3. Be cautious in giving *atropia* to flaxen-haired, light-complexioned, nervous women.
4. Be cautious in the use of *morphia* subcutaneously after opiates or morphia have been given by the mouth or rectum.
4. *Chloral Hydrate* should be exhibited with great care.
6. Remember that children are especially susceptible to the narcotic action of opium and its alkaloids.—*Dr. King's Medical Prescriptions.*

Diabetes Following Extirpation of the Pancreas.

Minkowski has found that not only in dogs, but also in cats and pigs, a severe form of diabetes mellitus follows the entire extirpation of the pancreas. In birds this does not occur. In order further to show the special function of the pancreas, the author, after removing the pancreas from the abdominal cavity, has transplanted pieces of it under the skin of the abdomen. By so doing the appearance of the diabetes is checked, even after the entire removal of the pancreas from the abdomen; but if the transplanted pieces are subsequently removed diabetes soon appears.—*New York Med. Times.*

Indications for Intubation.

Scheniegelow, E. (*Jour. Lar., Rhin. and Otol*).

1. Cases of acute stenosis due to œdema of glottis.
2. Cases of diphtheria causing acute stenosis, when time not sufficient to perform tracheotomy.
3. When consent cannot be obtained to do tracheotomy.
4. In paralysis of abductors and in spasms of abductors.
5. In cases of acute stenosis from thyroiditis.
6. All cases of chronic stenosis.

Also intubation is an allowable procedure in all cases of acute stenosis of diphtheria.

On the Arsenical Treatment of Multiple Sarcomatosis of the Tegumentary and Mucous Surfaces.

The author reports the case of a young girl who had hard, transparent nodosities at the end of the nose, the angles of the eyes, upon the cheeks, the mucous surfaces of the lower lip, the palatine vault and the uvula. She had also numerous tumors in the thickness of the skin of the arms, varying from the size of a lentil to that of an almond. Pyrogallic ointment produced an amelioration which was followed by recurrence. The nodosities multiplied, their surface became tuberous and the superficial ones threatened to fungate. The spleen was very large. Under the influence of arsenical medication these tumors disappeared almost entirely—*Therap. Review.*

SURGERY.

The Present Position of Gall-Bladder Surgery.

Czerny, after a general consideration of gall-bladder surgery, presents the following conclusions:

1. Gall-stones require operation, if they cause frequently repeated or lasting trouble.
2. Empyema of the gall-bladder imperatively demands operation, as does hydrops, if it gives serious trouble.
3. The typical operation for gall-stones consists in incision, removal of the stones, and suture of the gall-bladder; in this, however, the abdominal wound should be drained for a short time.
4. If the cystic duct is closed, if the gall-bladder is the seat of inflammation, or the contents are greatly altered, then a temporary gall-bladder fistula must be made.
5. Extirpation of the gall-bladder is indicated only in cases of severe inflammatory carcinomatous involvement.
6. When the ductus choledochus is closed, the operation is absolutely indicated, if the strength of the patient will permit. If one does not succeed in removingthe stone or obstruction, then it is recommended to produce a fistula between the gall-bladder and duodenum.
7. The best incision for gall-bladder operations is an ⌋ shaped cut; the vertical limb lies in the linea alba, and the horizontal part runs towards the right, just below the level of the umbilicus.
8. The danger to life of gall-stone operations will be probably less than in operations for vesical calculus.—*Epitome of Medicine.*

Watson (Francis Sedwick) on the Treatof Bubo.

This paper is a plea for the treatment of bubo by excision, and the subsequent attempt to obtain primary union.

Twenty-two buboes were treated, and in ten, a little less than one-half, perfect union by first intention resulted.

As regards the technique of the operation, the most important points are as follows:

1. To remove thoroughly all diseased tissue, and to leave, as far as possible, a perfectly healthy surface in every part of the wound.
2. To remove all portions of the skin, which are, or threaten to become necrotic.
3. To curette the under surface of the skin flaps.
4. To thoroughly swab the whole surface with dry sterilized gauze or sponges wet with a solution of corros. subl. 1.4000.
5. To tie, as far as possible, the end of all lymph vessels that have been divided.

The author considers this last point of especial importance, and one which has not hitherto been attended to. If not ligated, these vessels pour into the wound a large amount of fluid which lifts up the flap and lessens the chance of primary union. These vessels closely resemble cutaneous nerve branches, but are distinguished from them by having a distinct lumen, from which clear fluid exudes, and are of a more yellowish color, and present a duller surface.—*Jour. Cut. and Ver. Dis.*

GYNECOLOGY.

The Significance of Vaginal Discharges.

A leucorrhœa inodorous or of mild odor persisting during the climacteric, accompanied by increasing hemorrhage, is suspicious, and demands investigation.

A leucorrhœa profuse, of peculiarly fetid odor, grumous, excoriating, appearing early or late during the climacteric, with profuse hemorrhage, is reasonable evidence of cancer of the cervix.

A leucorrhœa moderate in amount, ill-smelling (the peculiarly fetid odor of cancer of the cervix being absent), accompanied by hemorrhage, suggests cancer of the corpus uteri.

A leucorrhœal discharge with hemorrhage containing material like the washings of meat, is said to indicate sarcoma.

A watery discharge, as a rule, occurring during menstruation, odorless or of little odor, persisting, accompanied by profuse hemorrhage, indicates fibroids; with little or no hemorrhrge, polypi. Profuse bloody discharges coming on gradually with declining menstruation, ceasing usually with the menstrual flow, point to fibroids. Persistent profuse discharges of blood occurring spontaneously, arising from sudden exercise or coition, occurring; as a rule, after the menopause, indicate cancer.

A gradually increasing amount of menstrual flow is suspicious and needs investigating. "Post-climacteric hemorrhages in a fibroma of the uterus of long standing, form one of the principal grounds for the suspicion of sarcoma." (Borner.)

The early recognition of malignant disease and the possible prevention of that fatal exhaustion which accompanies it by the administration of drugs, and the application of those methods which, in a measure, may be supposed to offset the terrific drain on the nervous system, inasmuch as present experience shows that early removal of diseased tissue prolongs life, and the importance of early diagnosis and treatment can hardly be over estimated.—*N. E. Med. Gazette.*

The Decidua in the Diagnosis of Extra-uterine Pregnancy.

Ayers from microscopical studies of the normal and diseased endometrium, reaches these conclusions: In cases of ectopic gestation the endometrium is usually transformed into decidua. This decidual tissue is pathognomonic of pregnancy. It may be removed with the curette for examination under the microscope, which, however, merely reveals the presence of the characteristic cells. The clinical history will then determine whether the condition is intra- or extra-uterine pregnancy.—*Amer. Jour. Obstetrics.*

NEWS AND MISCELLANY.

The Pan-American Medical Congress.

The Section in Marine Hygiene and Quarantine has been organized as follows: Honorary presidents: Dr. Lino Alarco, Lima, Peru; Dr. Henry B. Baker, Lansing, Mich.; Dr. Cardenas, Managua, Nicaragua; Dr. J. J. Cornilliac, St. Pierre, Martinique, F. W. I.; Dr. Felix Formento, New Orleans; Dr. H. B. Horlbeck, Charleston; Lieutenant Colonel Amalio Lorenz, Sub-inspector of second class Spanish Navy, Havana; Dr. F. Montizambert, Quebec, Canada; Dr. Francisco Nunez, St. Tecla, Salvador; Dr. Juan Ortego, Guatemala, Guatemala; Dr. Joseph Y. Porter, Jacksonville, Fla.; Dr. John Pringle, Kingston, Jamacia; Dr. Juan J. Unoa, San Jose, Costa Rica; Dr. J. Mills Browne, Surgeon General, United States Navy. Executive president: Dr. Walter Wyman, Surgeon General, United States Marine-Hospital Service, Washington. Secretaries: Dr. S. T. Armstrong (English-speaking), 166 West Fifty-fourth Street, New York; Dr. G. M. Guiteras (Spanish-speaking), United States Marine-Hospital Service, Washington. Advisory Council: Dr. H. M. Biggs, New York City; Dr. John C. Boyd, United States Navy; Dr. H. R. Carter, Norfolk, Va.; Dr. W. M. L. Coplin, Philadelphia; Dr. A. G. Clopton, Galveston, Texas; Dr. C. G. Currier, New York; Dr. S. Durgin, Boston; Dr. Seneca Egbert, Philadelphia; Dr. George Homan, St. Louis; Dr. W. T. Jenkins, New York; Dr. J. F. McShane, Baltimore; Dr. G. H. F. Nuttall, Baltimore; Dr. S. R. Olliphant, New Orleans; Dr. Dabney Scales, Mobile; Dr. R. M. Swearingen, Austin, Tex.

The executive president desires to call the attention of all members of the medical profession that are interested in the topics pertaining to this section to the regulation of the congress, that contributors are required to forward, not later than July 1st, to the secretary of the section, abstracts, not to exceed six hundred words each, of the papers they propose to present before the section.

The topics that will be considered by this section are as follows: 1. The hygiene of vessels, commercial or naval, including the questions of ventilation, heating, sanitary arrangements, the disposal of cargo so as to facilitate disinfection, food supply, etc. 2. The medical officers of passenger vessels; methods for their selection, duties, etc. 3. The vital statistics of seamen and firemen. The question of the medical examination of crews preparatory to shipping. 4. The supervision of vessels by government medical inspectors at ports of arrival and of departure. Code of rules for handling an epidemic disease that breaks out on shipboard. Disinfection of passengers and crew during a voyage. Location and arrangement of ships' hospitals. 5. Epidemic and exotic diseases propagated by shipping. What diseases should be quarantined. Responsibility of nations for epidemics; India for cholera, South America for yellow fever. Can a feasible plan be devised to totally exterminate cholera? International intervention to prevent the propagation of cholera and other epidemic diseases by pilgrimages or immigration. 6. International uniformity in quarantine regulations. Should quarintine officers be notaries public? 7. Arrangement of detail and equipment of quarantine stations: *a*, inspection stations; *b*, local quarantine stations; *c*, refuge stations. Methods for handling infected or suspected vessels. Interstate and inland quarantine: sanitary cordons; camps of refuge; camps of probation. Recent improvements in hospitals for infectious diseases. Railroad inspection and quarantine. Length of time vessels should be held in quarantine. Conditions that should determine proclamation of quarantine against a country. Under what requirements may passenger traffic be carried on between a port infected with yellow fever and a Southern port of the United States during the summer with the least obstruction to such traffic? What merchandise should be considered as requiring treatment if shipped from a port or place infected with cholera, yellow fever or small-pox? 8. Methods of disinfection: *a*, persons; *b*, baggage; *c*, cargoes; *d*, vessels. Recent improvements in quarantine appliances; steam chambers; sulphur furnaces. Liquid sulphur dioxide as a disinfectant. Treatment of ballast: water; solid. What time should a disinfected vessel be detained in quarintine? *a*, for cholera; *b*, for small-pox; *c*, for typhus fever; *d*, for plague; *e*, for yellow fever. Methods of disposal of the bodies of those who die while in qurantine.

ARMY AND NAVY.

U. S. ARMY, FROM APRIL 30, 1893, TO MAY 6, 1893.

A board of Medical Officers to consist of Lieutenant George M. Sternberg, Deputy Surgeon General; Lieutenant Colonel William D. Wolverton, Deputy Surgeon General; and Major Joseph R. Gibson, Surgeon, is appointed to meet at West Point, N. Y., June 1, 1893, or as soon thereafter as practicable, for the physical examination of the cadets of the graduating class at the U. S. Military Academy, and such other cadets of the academy, and candidates for admission thereto as may be ordered before it.

By direction of the acting Secretary of War, leave of absence for three months and fourteen days is granted Major John H. Janeway, Surgeon U. S. Army.

Captain Henry S. Turrill, Assistant Surgeon, U. S. Army, ordered to report in person to the president of examining board at Omaha, Nebraska, for examination, with a view to determine his fitness for promotion as contemplated by the act of Congress, approved October 1, 1890.

Colonel Charles T. Alexander, Assistant Surgeon General is detailed as a member of the Army Medical Board, vice Colonel Charles H. Alden, Assistant Surgeon General hereby relieved.

THE POSITION OF STRONTIUM IN THERAPEUTICS.

JOHN V. SHOEMAKER, A. M., M. D.*

Pharmacology.—As regards its chemical properties strontium is intermediate between barium and calcium. Though not an abundant element it is found in nature associated with both the metals mentioned. The principal native forms in which strontium occurs are the sulphate, called celestine, from its sky blue color, and the carbonate, known as strontianite from the place of its discovery, Strontian, in Argyleshire, Scotland. The carbonate was found in 1787 and was at first regarded as a carbonate of barium. Crawford, in 1790, advanced the idea that the new mineral contained an alkaline earth. Strontium was distinguished as an element by Hope, in 1792, and independently by Klaproth, in 1793. Sir Humphrey Davy isolated the metal in 1808, but owing to the faulty process which he employed, did not obtain it in a state of purity.

Strontianite is found in other places in Scotland; in Salzburg; Saxony and Westphalia; in Schoharie, New York, and other places in the United States. Calcium is often, and barium sometimes, present in this mineral. Celestine occurs in various parts of England, in the sulphur mines of Girgenti and other places in Sicily, in Hungary, Salzburg and near Paris. It is abundant in Strontian, or Green Island in Lake Erie. Celestine often contains barium or calcium.

The relation between barium and strontium is analogous to that between sodium and potassium. The strontium salts are between those of barium and calcium in specific gravity. They resemble those of barium in their physical and chemical properties. The salts of strontium are not, however, like those of barium, precipitated by silico-fluoric acid or hyposulphite of sodium. They communicate a brilliant, purple-red color to flame.

From the close association of barium with strontium, the similar composition of the mineral forms in which they occur and the parallelism between their salts it has been no easy task to procure pure salts of strontium. An admixture of barium clings to most products and it has been found especially difficult to remove the last trace of this contamination. On account both of its source and chemical relationships an investigation of the physiological action of strontium was long delayed. It was either condemned as sharing the toxic properties of barium or neglected under the supposition that its influence was comparable to that of calcium. The metal was, therefore, regarded as being only suitable for the manufacture of dyes and fireworks. It is to a French chemist, Paraf-Javal, who has been since 1886 engaged in the preparation of a beautiful strontium chromate for dyeing purposes that we owe the introduction into pharmacy of chemically

*Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine, and Clinical Professor of Diseases of the Skin in the Medico-Chirurgical College of Philadelphia; Physician to the Medico-Chirurgical Hospital.

pure salts of strontium. A delicate test for the presence of barium in a solution of a strontium salt is the addition of a few drops of a solution of the bichromate of potassium. This will reveal the presence of even $\frac{1}{2000}$ of barium and will not precipitate the strontium.

Strontium combines freely with other elements and the list of its salts is a long one, embracing, in addition to those already mentioned, the oxide, borate, phosphate, phosphite, sulphide, sulphite, hyposulphite, iodide, bromide, chloride, nitrite, nitrate, lactate, acetate, benzoate, etc. Of these the bromide, the chloride, the acetate and the nitrate are soluble in one and one half parts of water, the iodide in two parts, the benzoate in fifteen parts. The borate and the phosphate are insoluble.

Physiological Action.—It is but recently that the salts of strontium have been subjected to a careful investigation. It had, indeed, been noted by careful observers that, though the oxide of strontium is obtained in the same manner as the oxide of barium, which it closely resembles, yet the former combination is harmless while the latter is toxic when taken into the system. Gruelin, in 1824, made some experiments on rabbits and concluded that strontium and its soluble salts are perfectly harmless. In his "Handbook of Chemistry" he remarks that these salts are not poisonous unless they contain a poisonous acid. Brunton declares that strontium increases the contractile power of muscular tissue and also the duration of the contractions. He believes that these effects are increased by combination with calcium.

Our principal knowledge upon this subject is due to Dr. J. V. Laborde, Chief of the Physiological Laboratory of the Faculty of Medicine, of Paris, who conducted a series of investigations extending through a period of six months. The results were announced at meetings of the Academy of Medicine, July 21st and 28th, 1891. His experiments were made upon dogs and, in one instance, upon the human subject. The drug was introduced by means of intra-venous, hypodermic and intra-muscular injections and also into the stomach by the œsopageal sound. To a rabbit weighing only five pounds, seven and one half grains of the chloride were given with absolutely no result. On the other hand, the chloride of barium, as indicated long ago by Gruelin, Rabuteau and Orfila, is very toxic. Thirty grains of carbonate of strontium were productive of no results in a man. The lactate of strontium was given with impunity and in the dog occasioned marked diuresis. The corresponding salt of potassium possesses toxic power. The bromide of strontium is far better tolerated by the stomach than the bromide of potassium and may be given in considerable doses to man without any ill consequences. M. Chas. Féré, in an independent investigation relative toxicity of the bromides when given by intra-venous injection, ascertained that in the rabbit the bromide of potassium is about five times as toxic as the bromide of strontium. Eighteen different bromide combinations were studied by M. Chas. Féré as regards comparative toxicity. In his tabulated results the bromide of barium stands fourth in the order of toxicity, while the bromide of strontium is sixteenth, of lithium seventeenth and of sodium eighteenth.

The salts of strontium in general are like those of calcium in being innocuous although the latter may produce vomiting when injected into a vein while the former are free from this effect. Strontium increases the appetite, digestion and assimilation of animals, who gain in weight under its use. Its salts retard fermentation and putrefaction and act as intestinal antiseptics. Laborde attributes to them an anthelmintic effect upon the ground that in all his post-mortem examinations of dogs he never discovered any traces of tænia or other parasites. According to the experiments of Dr. Amand Malbec, the nitrate of strontium is a good diuretic. This writer is of the opinion that the sulphate, especially the latter, may be utilized as antiseptics, antiparasitics and restoratives.

The salts of strontium are partially eliminated in the urine and fæces but a portion is retained with the economy and deposited in the bones, liver, and, to a less extent, in other soft tissues. Though elimination begins later there is less accumulation of the bromide of strontium in the organism than of the corresponding salt of potassium.

Therapy.—Strontium is a constituent of many, if not all, mineral springs, and a portion of their beneficial influence may

probably be ascribed to this element. The bromide, the lactate and the iodide are the salts with which thus far the most numerous clinical experiments have been made. These salts, prepared by Paraf-Javal and solutions made by the well known pharmacists of Paris, are now upon the market, the agents for the United States being E. Fougera & Co., of New York. Specimens of these preparations and others made by John Wyeth & Brother, of Philadelphia, and by McKeller & Robbins, of New York, have been placed in my hands for experiment.

The bromide of strontium is in the form of colorless, crystalline needles or grains, which melt with decomposition at a red heat. From the aqueous solution the salt separates in long needles which do not effloresce in dry air or even over oil of vitriol. When heated they melt in their water of crystallization and then give it off. They are easily soluble in water and somewhat so in alcohol. They have a slightly saline and somewhat bitterish taste and are destitute of smell. The bromide of strontium is incompatible with the bicarbonate of sodium, the carbonate of strontium being precipitated.

The solution of the bromide is neutral, permanent, clear, colorless and without smell. It has a saline but by no means disagreeable taste.

The lactate of strontium appears in the form of white granular masses. It has a warm, alkaline and slightly bitter taste and is without odor. The solution is a clear and colorless fluid and has a warm, acidulous, agreeable taste. The iodide of strontium occurs in small white crystals with an acrid saline taste.

Upon the announcement by Dr. Laborde of the results of his study of the physiological action of strontium, clinical experiments were at once begun by several of the physicians attached to the hospitals of Paris. As far back as 1885 Ismail Hassan had announced that the nitrate was of service in chronic rheumatoid arthritis, but his declaration seems to have passed unheeded. It had also been said that the iodide is useful in cardiac disorders. M. Laborde, believing that the bromide of strontium might advantageously replace the bromide of potassium, administered the former drug in epilepsy in doses from 75 to nearly 200 grains *per diem*, the latter quantity being the largest which would be tolerated. In moderate doses it has no irritant effect and in fact, is rather of assistance to digestion. It is consequently much better borne than the potassium salt. Dr. Chas. Féré has related the case of a patient under his care at the Bicêtre treated with 10 grammes (155 grains) of bromide of potassium daily, in whom a cutaneous eruption persisted in spite of intestinal antisepsis. Upon the strontium being substituted for the potassium salt equally good results were obtained without the production of any undesirable symptoms. M. Féré has, in some cases, exceeded 200 grains a day without observing any evil consequences. Dr. Dujardin-Beaumetz also attests the fact that the bromide of strontium is better borne than the other alkaline bromides. Its therapeutic efficacy has been found by M. Féré equal to that of the other bromides used in that disease. Germain Sée has likewise found it of use in epilepsy. Constantin Paul administered 90 grains daily to a young woman who was subject to attacks of hystero-epilepsy at each menstrual period. After the bromide of potassium had been used without effect in daily doses of 60 grains it was replaced by the strontium salt in doses of 90 grains a day. In the two months during which she had taken the latter remedy the attacks had not occurred. At a meeting at the Academy of Medicine, Oct. 27, 1891, M. Sée remarked* that the diuretic effects of the salts of strontium observed by M. Laborde in the dog had not been verified in the human subject. But in those suffering from diseases of the kidneys and heart the digestive disturbances have been notably ameliorated. This fact led him to make use of strontium in affections of the stomach. He had administered the bromide in daily doses of 30 to 60 grains, given during the three meals. In 32 cases of dyspepsia, many of which were associated with excess of hydrochloric acid, rapid and decided relief was obtained, especially in regard to diminution of flatulence. In 8 cases where hydrochloric acid was deficient the remedy produced the same effect as in those attended by excess of chlorine or hydrochloric acid, free or combined. In 6 cases, one of which was of nervous vomiting, the relief was complete. Dr. G.

* See *Medical Bulletin*, January, 1892, p. 17.

Coronedi, of Florence, obtained an excellent result from the administration of the bromide of strontium in an obstinate case of vomiting of pregnancy. He gave 15 grains after each of the two principal meals and the remedy was continued for a month, at the end of which time the gastric inability had almost entirely disappeared and the treatment could be discontinued. The same writer reports favorably of the bromide of strontium in vomiting from dilatation of the stomach, acute gastric catarrah, hysteria, and other conditions. He gave it in unleavened bread immediately before each meal.

M. Sée has seen the bromide of service in Bright's disease. It has not been known to occasion any bromine rash.

A combination known as bromo-strontium has been prepared, a teaspoonful of which contains 12 grains of bromide of strontium and ½ grain of hydrobromate of caffeine. Bromo-strontium has been employed with success in nervous headache, gastric irritability, vomiting of pregnancy, hysterical conditions, etc.

The lactate of strontium is of decided service in albuminuria. M. Constantin Paul thus summed up his experience of five months use in these cases. "Among my patients it generally caused a rapid reduction of the albumen to one-half. Continued for a month the albumen constantly decreased and at the end of that period the remedy could be suspended. The amount of albumen did not then augment but remained. In a case of nephritis, probably amyloid, in a patient suffering from suppuration and fever the result was excellent. In some rare cases the salts of strontium fail to produce a good effect. Strontium is not diuretic. If its exhibition is too soon discontinued the albumen increases. It is indicated in rheumatic parenchymatous nephritis, scrofulous and gouty nephritis and in the albuminuria of pregnant and puerperal women. The remedy is of no service after the manifestation of uræmia." In illustration of the harmlessness of pure strontium the same writer states that he had himself taken 774 grammes of the bibasic phosphate of strontium in 111 days, or about 100 grains a day. He has likewise found the lactate beneficial in albuminuria of cardiac origin. He generally administers it in daily doses of 90 grains, divided into three portions, though he has found it well borne even in daily doses of 120 to 160 grains. Together with adminished excretion of albumen the general symptoms and condition of the patients improve. M. Dujardin-Beaumetz has used the lactate in albuminuria due either to renal or cardiac disease. Within a few days the albumen was diminished to one-half its former amount. This high authority explains the favorable action of strontium by its beneficial influence upon digestion, the amount of toxic material formed in the gastro-intestinal tube being reduced to a minimum. He concludes that in lactate of strontium we possess an invaluable agent, the action of which is at the same time certain and inoffensive. Dr. Bucquoy obtained similar results from the administration of the lactate in albuminuria.

Dr. Ménager has recently reported a favorable action of the lactate in a case of albuminuria with œdema occurring during pregnancy. A pronounced diuretic effect was produced and the dropsy subsided.

The lactate of strontium has also proved of service in dyspepsia and dilatation of the stomach. It is said to have been used with benefit in diabetes.

The nitrate of strontium has been used in 30 grain doses in rheumatism of the joints and the acetate as a tœniafuge in doses of 2 to 4 drachms daily.

Since receiving samples of the chemically pure bromide, iodide and lactate of strontium I have employed them in many cases to which they seemed adapted. The results have, for the most part, been decidedly encouraging though in some the element of time has, of course, been too short to warrant me in expressing absolute confidence in the duration of the improvement. I shall continue my observations as opportunities offer. I subjoin a brief description of certain selected cases in which I witnessed marked benefit from the use of strontium.

In a case of advanced Bright's disease, accompanied by eczema, an abundance of albumen in the urine, œdema of the lower limbs, embarrassed respiration and irritability of the stomach and bowels, notable amendment took place within two weeks from administration of the lactate, in 30 grain doses four times a day. The eczema and the œdema entirely disappeared, the respiration improved and the urine contains much less albumen. The

irritability of the mucous membranes has diminished. The patient is able to take more food, his digestion is better and his sleep more sound and refreshing. In this case all the usual remedies had been tried in vain.

The lactate produced amelioration in several cases of subacute or chronic gout and rheumatism, manifested by stiffness and pain of joints, muscular pains and an excess of uric acid. The pains were greatly relieved, the turbid urine became clear, the tongue more clean, digestion better and the bowels more regular. I gave the drug in doses of 10 to 30 grains from four to six times a day. Although the results, in these cases, were more satisfactory from the lactate, the bromide also, given in the same doses and at the same intervals, was of efficacy. Contrary to the statement of M. M. Sée and Constantin Paul my attention was called to a pronounced increase in the quantity of urine passed though this result did not occur in all cases. Many of these were cases in which treatment by means of salicin, salicylic acid or the iodide of potassium had been used without avail or in which they had even done harm by damaging the digestion. This, as every one knows, is an exceedingly intractable class of cases and if the lactate of strontium can exert a beneficial influence upon a considerable number of these it must be regarded as an important addition to our therapeutical armamentarium. In patients of a neurotic type or in whom the nervous system had been gravely impressed I derived better results from the exhibition of the bromide.

The iodide was of service in three cases of chronic eczema attended by considerable infiltration and thickening of the skin and clearly dependent upon the rheumatic diathesis. In one case there was articular involvement, in another, well-marked lumbago and pains in the limbs, while the third was characterized by fleeting muscular pains in different parts of the body. In one of these cases the eruption has entirely disappeared, while in the remaining two a gradual improvement is manifest. Suitable external treatment was conjoined.

A case of psoriasis due to a rheumatic diathesis is improving under the administration of 30 grains of the iodide of strontium five or six times a day. Infiltration is lessening, uric acid disappearing from the urine and the flying muscular pains decidedly ameliorated. I express no opinion regarding the durability of the amendment.

The lactate proved efficacious in a number of cases of chronic gastric and intestinal catarrh. The remedy was well borne and seemed to promote nutrition. It was given in doses of 10 to 20 grains three or four times a day between meals.

In nervous dyspepsia and gastralgia marked relief followed the exhibition of the bromide of strontium, given in doses of 10 increased to 30 grains three or four times a day.

One case of chorea was much benefited by the bromide. The patient was a child, nine years of age, whose nutrition was decidedly impaired on account of the constant twitching which rendered mastication difficult and interfered with sleep. The dose was 10 grains, increased to 15 grains and repeated two or three times in the course of the day.

In a case of spinal neurasthenia of long standing, accompanied by attacks of pain in the back and limbs, headache and insomnia, 10 grains of the bromide at bedtime effectually relieved the pain and secured a good night's rest.

In a case of that rebellious malady, parasthesia in an aged person, (senile pruritis) a happy effect followed the administration of 30 to 40 grains of the bromide. Itching, indeed, was not abolished but was notably relieved, so that the patient experienced tolerable comfort and was able to sleep much better than formerly.

From these experiments it would seem without doubt that in cases of chronic rheumatism, gout, gastro-intestinal catarrh and albuminuria strontium deserves extended trial. Failure of other remedies should indicate its use. The bromide of strontium is very well adapted to replace the bromide of potassium in the treatment of epilepsy, being at least as efficient and often better tolerated.

CHANGED HIS NAME.—"Howdy-do, Hogg!"

"My name is Bacon, sir."

"Beg pardon; but I felt sure you were Mr. Hogg, the invalid."

"So I was; but I have been cured."—*National Tribune.*

CLINICAL LECTURES.

CEREBRAL SPASTIC PARALYSIS.*

DE FOREST WILLARD, M. D.†

We have to-day two very interesting cases of spastic paralysis which require operation. These represent the two extremes, one being a mild case in which there is a slight paraplegia with not much mental impairment, and the other being one of those severe grades of the affection, in which there is a marked general spastic condition of all the muscles of prehension and locomotion, and in which the mind is in a condition of imbecility and stupor. Between these two types there exists every degree.

Case I. The first patient is a white boy of five years, whose parents are both living and well. No history of deformity or paralysis can be elicited, but he is the youngest of seven children, six of whom have died under five years of age, the cause of death being diphtheria in two, teething in three and jaundice in one instance. He was born at full term, without instruments, and has never been ill. About three years ago his parents noticed that his ankles were weak, for which he was treated at the Orthopædic Hospital in this city, and for which braces were prescribed, which he has since worn. The parents noticed that his knees were stiff and that he walked on his toes.

Upon examination the feet are found extended, and upon attempting to flex the foot upon the leg, the calf muscles become tense, and if gentle force be continued the foot may be flexed. Upon removing the hand the foot again extends. The flexion of the foot under firm pressure is peculiar and differs from ordinary contracture from paralysis, which would allow the foot to extend as far as a given point but not beyond it. In flexing the foot the muscles seem to give way to the moderately firm pressure of the hand as a piece of lead bends, and on this account, this form of contracture is known as "lead pipe contracture." On flexing the knees the same rigidity of the muscles is by means of walking shoes his condition can be much improved. The hamstring tendons will not require division, but the apparatus will have to be carried above the knee and secured to a thigh band, the knee-joint being a lock-joint which will fix the knee in the extended position, but which may be temporarily relaxed to flex the leg when sitting.

Operation. The patient being etherized, and the parts having been previously prepared, a puncture was made with a sharp-pointed tenotome and a probe-pointed tenotome was introduced into the inner surface of the tendo-Achilles about one inch above the insertion. The tendon was put on the stretch by the assistant, the cutting surface of the knife was turned forward, and the tendon was divided by a gentle, rocking motion. As soon as the division was accomplished, the tenotome was turned flatwise and withdrawn, the puncture being closed with a small pledget of antiseptic gauze dipped in a 1:1000 bichloride solution. A piece of dry gauze, cotton and an antiseptic roller bandage were applied, and the foot, in a slightly over-corrected position, was fixed with a plaster of Paris dressing.

Case II. The second case is a small white boy only three years of age. His father is alive and healthy; his mother is also living, but delicate since the birth of this child. The child has never been strong since he had scarlet fever. There is no history of deformity or nervous disease in the family. While carrying this child the mother had a fall at the seventh month; the waters broke, but no other injury was noticed at the time and the gestation progressed uninterrupted to full term. The labor was very prolonged; observed, but not to so great a degree. The deformity is due to some cerebral injury or disease which has left this irritable condition of the muscles.

In this case the prognosis is very favorable, and after the tendo-Achilles has been divided on both sides, the feet can be brought squarely upon the ground, and

* Reported by Dr. James K. Young.

† Clinical Professor of Orthopedic Surgery in the University of Pennsylvania, etc.

the breech presented for several hours and became black from pressure and cyanosis. At first the limbs were very flexible, but during his third year they began to grow rigid when moved. On examination all his extremities exhibit well-marked spastic condition when moved; the right side is more affected than the left. The child is well nourished and plump. His general physical condition is otherwise favorable; his mental condition, however, is seriously impaired. His expression is vacant, his attention is attracted with difficulty, and he does not attempt to express himself in words. He has marked strabismus.

This case represents an extreme grade of the affection. The prognosis must of necessity be a guarded one. Operations will improve the condition of the limbs, and the mental condition also may to a degree be considerably improved by permitting him to mingle with his fellow creatures. It is impossible to remove the primary lesion, and when one set of muscles is operated upon, the spasm may be increased in other sets of muscles. In some cases, as in one recently seen, all the voluntary muscles, even the muscles of the tongue, are affected. In these cases, in addition to the operations, massage and other local treatment that may be employed, it is necessary to make a special effort to educate the mind. The child may be sent to a special institution for the education of the feeble-minded, to a private institution of the same character where only a limited number are taken, or a private tutor may be appointed. Under such training it is remarkable how much improvement may be attained.

The present case will require a number of tenotomies, and to-day we will perform section of the adductor tendon, which is the operation most required. This is best accomplished at its insertion into the pubic portion of the os innominatum, the insertions of the adductor longus and brevis being the ones most frequently contracted. The tendons are put on a stretch by separating the limbs as widely as possible. The puncture is then made upon the outer margin of the stretched tendon, a probe-pointed, broad-faced, convex tenotome is inserted flatwise, its cutting surface turned against the tendon, and with a slight rocking motion the division is accomplished, care being taken to protect the skin.

Operation. The patient having been etherized and the parts having previously been rendered aseptic, the parts were put upon a stretch, and with a sharp-pointed tenotome the puncture was made at the outer border of the tendon half an inch from its insertion into the ramus of the pubes. A probe-pointed convex tenotome was carried flatwise behind the tendon, its cutting face turned inward and the section made. The tenotome turned flatwise was withdrawn, the puncture being covered with a small pledget of gauze and the whole covered with antiseptic gauze, cotton and a roller. The limbs are best secured in this separated position by means of a plaster bandage extending from the toes half way up to the thighs. This prevents flexion of the knees, and the feet are securely tied by means of a muslin roller bandage. This simple method is more efficient than the more complicated apparatuses sometimes employed.

Why Good Swimmers Drown.

The *Northwestern Lancet* offers a new explanation of the sudden drowning of good swimmers, hitherto attributed to cramp. There is nothing in a cramp in a leg to prevent an ordinary swimmer supporting himself in the water by his hands or on his back, nor to cause him to throw up his hands and sink once for all like a stone. The cause is attributed to perforation of the ear drum, through which the access of water pressure occasions vertigo and unconsciousness, and a practical caution results, to persons having such perforation, to protect their ears with a stopper of cotton when bathing.

The Creator Knows. — "Doctor," said the patient, "I believe there's something wrong with my stomach."

"Not a bit of it," replied the doctor promptly. "God made your stomach and He knows how to make them. There's something wrong with the stuff you put in it, may be, and something wrong in the way you stuff it in and stamp it down, but your stomach is all right." And immediately the patient discharged him.—*Amer. Anal.*

COMMUNICATIONS.

EXTRA-UTERINE PREGNANCY.*

DR. MORDECAI PRICE., Philadelphia.

Preliminary to the discussion of the subject to which I shall call your attention I feel it appropriate to mention the fact that of the many operators in abdominal surgery, who have left indelible proof of their well-earned reputations in ovariotomy, the pioneers in abdominal surgery, its first successful workers, few if any of them recognized this dangerous condition as one that could be removed by the very same power they were so fond of applying in other and less dangerous conditions.

Many of us lay claim to originality in procedure, while the fact exists that all that is best in our work can be directly traced to that genius of the surgery of our generation, Mr. Tait. He has taught us the best of the little we know. From the lessons his own work in abdominal surgery taught him he took up and perfected a work long neglected. I forbear calling your attention to what had been done by other men. Mr. Tait has done more to forward the cause of enlightened and skillful surgery than any man of his own or any other generation. It is the afflicted woman and the profession who should appreciate his great worth. In extra-uterine pregnancy alone he has saved more lives than some of the great battles of the war destroyed. It is to be hoped that with the profession the talk about originality will be modestly tempered; they are most thoroughly learned in these lessons who have had most experience in their application. Casting aside all claims of originality I will call your attention to the result of lessons in one hundred cases of extra uterine pregnancy. From my observations in these cases I second Mr. Tait's opinion that they are all tubal in origin. That the rupture takes place during the first twelve weeks in the greater number of the cases. I know of none later in the cases coming under our care.

Symptoms in extra-uterine pregnancy present a picture which once seen and appreciated cannot be forgotten by any one who has ordinary surgical sense. The symptoms of the disease are, in most cases, well-marked, absence of a period, a soft cervix, severe pain, agonizing at times, with fainting, in many cases death like pallor, a feeble and almost pulseless condition, distended abdomen, diarrhœa with no relief of symptoms, a constant desire to stool, the patient often found in the water closet in an unconscious condition owing to the great loss of blood from straining efforts at stool.

A feeling of fullness and weight in the pelvis, a boggy, fluctuating mass in Douglas' pouch, at times a tumor at one side or the other, or both. It is the pressure of this blood tumor on the bowel that compels the patient to make efforts to stool for its expulsion.

In recent cases well-marked symptoms of peritonitis have existed without increase of temperature. In more chronic cases where there have been a number of attacks with repeated bleeding from the ruptured tube with encapsulation; blood is a foreign body in the peritoneum and nature always makes an effort to protect itself from dangerous invasion from any irritant or poison.

Where the old clot is breaking down and the tube undergoing necrosis, there will be an increase of temperature. In my own personal experience in fifteen cases operated on with twelve recoveries, all of them emergency cases, almost all of them at the time I first saw them were supposed to be dying; pulse could not be counted at the wrist, almost every symptom here noted was present. I have assisted my brother, Dr. Joseph Price, with most of his cases, now eighty-five in number (one death),and I have yet to see a single case of intra-peritoneal hæmato-ceale. We have found the child in all cases of recent rupture, and rupture not over two weeks old, and also the placenta with its peculiar appearance and odor. In one month in the year 1891 we had eight cases of ruptured extra uterine pregnancy, the

* Presented to the State Med. Soc., 1893 and reported by Special Correspondent.

child was found in seven, the eighth was a chronic case of Dr. Dunham, of Trenton, N. J., that had ruptured eleven weeks before in the hands of a man that did not suspect the real cause of her trouble and when Dr. Dunham was called to the case she had a blood tumor extending to the umbilicus, accompanied with daily chills, contents very offensive with a large necrotic placenta. In this case we did not find the child, and I have no doubt it had been removed by absorption as many of them are. This patient recovered. The inflammatory diaphragm would not let the bowels descend to fill up the pelvis, so we left the cavity full of boiled Trenton water with a glass drainage tube to finish the good work, with watchful care of her attendant. She made a satisfactory and rapid recovery.

The case to which I wish specially to call your attention is one of extra uterine pregnancy operated on in the tenth month. Her attending physician was Dr. James Collins, a surgeon of well known reputation in this state and a member of this society. From the meagre history we could gather of her case she became pregnant about the first of January, 1892. February 13th, while shopping, she was seized with agonizing pain, was compelled to return home, fell on her doorstep and was carried in the house. Dr. George Yeomans attended her for three days but did not suspect pregnancy; not improving Dr. Yeomans requested that her regular attendant, Dr. James Collins, be called. She was then complaining of severe pains in the elbow joints, was much debilitated, as if suffering from mild sepsis. She slowly improved and the Dr. discontinued his visits. From this period on she suspected that she was pregnant.

Though ill she continued in the discharge of her domestic duties. Between the fourth and fifth months there occurred free hemorrhage from the uterus. She then doubted the possibility of pregnancy. About a month later she felt life; she was suffering severely but continued about her work, though losing flesh and strength daily and feeling herself a very ill woman. From the beginning to the end of her pregnancy she does not remember a single well day. She was taken in labor on the evening of the 21st of October; for three nights she had severe labor pain; there was no dilatation of the cervix until the 23rd. On the 23rd Dr. Collins concluded that there were serious complications in the case and suspected monsters, as two heads could be distinctly felt, one to the right and the other to the left; no part of the child could be detected in a careful examination through the cervix. It was determined to give the patient ether and do anything to help her that might be required by the child and the presentation. Dr. Collins in a very short time decided what he had to contend with and asked me to confirm his diagnosis of extra uterine pregnancy.

This was an easy matter—the womb was then wide open and empty—the hand passed in to the thumb and nothing but small clots of blood found in the uterus. The operation was a very short and simple one; the usual instruments for a section and the usual care to have things clean. An incision four to five inches long in the median line to the side of the placenta as near as we could judge of its location. The child had for its covering part of the placenta and its amniotic sac. It was delivered by the breach and passed over to Dr. Jennings, of Virginia, who took charge of the baby.

THE TREATMENT OF THE PLACENTA.

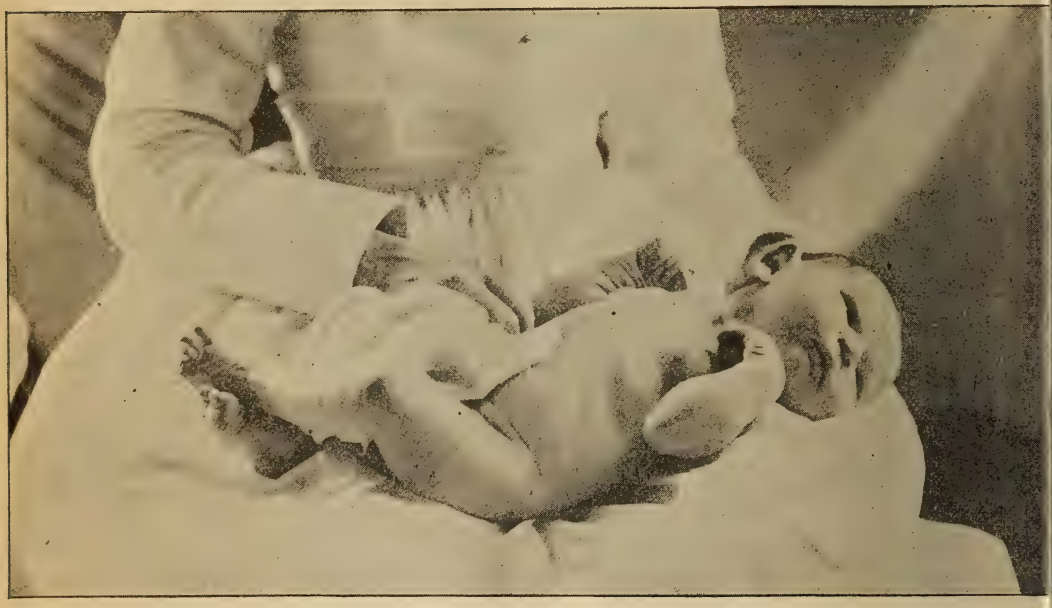
Before the operation the position of the placenta was to the left, the child in the center and the womb to the right. The placenta was attached to the uterine attachment of the left tube and the entire pelvic viscera of the left side from the spine at the back, extended up to the kidney and covered the descending colon. The placenta was slightly wounded in the abdominal incision, and was the cause of considerable hemorrhage. This was controlled by clamping forceps which were allowed to remain until the first dressing. The child was enveloped by the amniotic sac. To the amniotic sac was attached the transverse colon; also the small intestine to a small extent. In carefully examining and estimating the surface covered by the placenta those present concluded it was as large as the rim of a man's hat. The cord was attached about two inches to the left and the same distance above the umbilicus. The huge placenta vessels radiated in every direction toward the cord. The thought of removing the placenta in its peculiar position and size never once occurred to me, but

the knowledge of what would happen if the attempt was made did forcibly occur to me. The removal with such attachments could not have been other than of fatal hemorrhage.

The cord was then tied short where the amniotic sac was attached to the upper part of the wound, the general peritoneal cavity was opened, and the sac was stitched fast to the abdominal peritoneum. There was no amniotic fluid surrounding the child, all had been absorbed and the skin of the child undergoing digestion. This was shown as the least rubbing with a cloth would take off all the true skin and leave a raw and bleeding surface.

odor except that of creosote. The patient's temperature slowly advanced until about the 14th day, when her appearance indicated great danger from sepsis. An attempt was made to remove the placenta, but a slight detachment of it produced alarming hemorrhage which was controlled by pressure. In twelve hours the temperature dropped to 96°, and the indications were of a threatening character. At this time the opening in the abdomen gave no promise of the recovery of the patient; the membranes and placenta had a black and gangrenous appearance.

At the end of the third week the patient's condition seemed so desperate that



Child 4 days old. Delivered by Section by Mordecai Price, M.D., Oct. 23, 1892.

After the removal of the child the cavity in the amniotic sac was much reduced in size by the contraction of the surrounding muscles and viscera. These contractions were well marked. The sac was cleaned with gauze and packed all over the face of the placenta, and the ends brought out of the abdominal wound. Additional gauze was placed to keep the wound protected, iodoform was freely used and the first dressing was left for three days and then removed, and there-after twice daily until the patient recovered.

The drainage was free and consisted of blood and serum, perfectly free from all

we felt warranted in making a second attempt to remove the placenta, with the same result as in the first instance,—alarming hemorrhage. We then decided to cut away with the scissors all that portion of blackened placenta and membranes in sight. This was done daily, sometimes as much as one ounce at a time. All was removed until living placenta was reached. This continued until the thirty-third day when the patient seemed to be in severe labor, and part of the membranes from the left kidney presented themselves in the upper angle of the wound. The patient was suffering greatly from intermit-

tent paroxysmal pain. I would state that the placenta made a hard ridge of tissue, raising up the abdominal wall from an inch to 1¼ inches from the pubis to the left kidney, hard as a fibroid tumor and tender to the touch. This did not change in appearance until the thirty-third day, when spurious labor set in. We at once decided at all risks to remove the placenta. I passed my hand immediately back of the placenta over the kidney, finding its edge detached. I enucleated all the placenta except that attached to the uterus and left tube. This I could not tear away. The placenta tissue was living and bled freely. On the thirty-fifth day I removed the remainder.

At the end of the second week the amniotic sac over the transverse colon had sloughed away and a fecal fistula was the result. This complication continued to trouble us up to the sixteenth week. After the placenta was removed our patient gave us no further anxiety as to her recovery.

One of the strange features of Mrs. S. case was the fact that when ever the child was brought to her after the delivery, or was in sight, she become sick at the stomach. This continued for the entire period of the retention of the placenta, thirty-five days. She tried by every means to overcome it, she is a woman of wonderful will-power, a patient, child-loving, Christian mother, who felt it her duty to overcome such feelings. As soon as the placenta was removed, this symptom at once disappeared. She never would admit until after the removal of the placenta that the child's presence gave her both mental and physical distress. Had we known such to be the effect of its presence we would have removed it permanently from the room.

Child 7 months old. Delivered by Section by Mordecai Price, M.D., Oct. 23, 1892

CAUSES OF DEATH IN EXTRA-UTERINE PREGNANCY.

The most important cause of death is great loss of blood; the quantity lost is almost incredible and death, in some

cases, almost immediate; others only live a few hours, dying in great agony.

To perish by loss of blood is to be consumed by unquenchable fire; the burning thirst and intense pain cannot be described. I speak from my own experience, having once bled to unconsciousness from an open vessel after an amputation. The burning pain of the amputation was as child's play to the suffering from loss of blood. It is recorded by those who have attended cases of extra-uterine pregnancy, where the hemorrhage was so profuse as to destroy life in a few hours, as cramps, cholera morbus, uterine colic; in fact, every agonizing condition we may be called to treat.

Second, from pressure of the blood clot in the peritoneum; it takes much less fluid injected into the peritoneum to destroy an animal than if forced into the bowel, showing the direct destroying power in its pressure upon the sympathetic ganglions in the abdomen. The influence of blood pressure is well shown in cases of extra-uterine pregnancy where there has been great loss of blood, pulseless and apparently dying, abdomen distended with blood and clot; as soon as the abdomen is opened and the bleeding tube and blood-clot removed, the pulse will appear at once with regular and a distinct, countable beat, showing the influence of the pressure on the heart and other vital organs.

This fact we have noticed many times in our desperate cases. At time of rupture if the patient does not perish the peritoneum at once begins the removal by absorption of the blood-clot, placenta and baby, and I have no doubt there are many cases of recovery; but if this physiological work does not succeed, changes will take place, the contents will become poisonous, septicemia and its consequences will destroy the patient. Delays in operative measures in these cases make up the mortality list to the figure it now presents; could we operate promptly in all cases there would be only a very light death rate, say one to two per cent. These cases that have gone on to a later period and then have the child perish and the dead child become encapsulated, with such changes as time and a strong constitution can stand, with the placenta removed and so much of the earlier landmarks removed by the changes of time that we are unable to say anything of its earlier history save what the living ones have taught us as to the pathology of this dangerous condition; changes may and often do take place in these encysted, encapsuled extra-uterine pregnancies that will destroy life.

HEMORRHAGE.

No one doubts the possibility of hemorrhage in any part of the body, therefore, we may have intra-peritoneal hæmatocele, but the condition must be very rare, and its causes, as given by most admitted authorities on this subject, doubtful. Take the work of Dr. Joseph Price, and my own. We have never met with a case of intra-peritoneal hæmatocele in hundreds of operations done in the pelvis, and we have had hemorrhage from ruptured extra-uterine pregnancy one hundred times, and the cases we have met with exactly correspond with those described by Dr. Martin, under the heading of "Intra-peritoneal Hæmatocele." The day will come when Dr. Martin will change the heading of the chapter in his excellent work on the diseases of women from "Intra-peritoneal Hæmatocele" to Extra-uterine Pregnancy. I have no doubt that much of the confusion in the minds of the profession comes from the fact that this great surgeon continues to associate the symptoms of this most dangerous accident with a condition that in the experience of equally as good observers exists only as a very rare condition. I contend that we have absolute proof that the condition Dr. Martin calls intra-peritoneal hematocele is none other than extra-uterine pregnancy, for we operate for the identical symptoms and find ruptured tube, a placenta, and a baby in ninety per cent. of the cases, and other proof of pregnancy for the remainder.

There are a few important questions in regard to the treatment of extra-uterine pregnancy to which I would like to call your attention—conclusions drawn from my own experience. Such an occurrence as a rupture primarily into the broad ligament—I have never seen anything that in the least resembled it.

I have seen them develope in Douglas' pouch with the broad ligament covering its entire face as high as the umbilious and at the time of operation had we gone through the broad ligament in the removal of the product of conception, the

placenta and the retained blood clot, we would without doubt have concluded we had a broad ligament pregnancy. In our experience we have never met with a single case that had ruptured into the broad ligament.

Now in regard to the time for operation. In my opinion the operation should be done as soon as the diagnosis has been made—immediate surgical interference without regard to period of development or the viability of the child. I cannot agree with Mr. Tait in the following: "So long as an ectopic gestation was going after the period of primary rupture without risk to the mother, we should certainly not interfere."

I cannot conceive of a period in these cases where the extra-uterine gestation can go on without great danger to the mother. The placenta is daily enlarging and forming new adhesions and in every way increasing the risk of the mother. We hesitate to operate for the same reasons that we delay operating in large and complicated tumors—we know the great risk the patient has to take. The operator also feels that in a measure he may shorten his patient's life. Thus he wishes to shirk so much responsibility. We know by experience in all abdominal work that delays are dangerous. Extra-uterine pregnancy is no exception to this rule, but from its very beginning to the finish, there is continuous and increasing danger. No one here can question the advisability of an operation at the time of a first rupture for the control of the bleeding point and the removal of the condition producing and the cause of that danger; nor does the necessity for operation lessen from this dangerous period of rupture, but on the contrary continues to rapidly increase the danger to the mother. It is his duty to explain daily increasing danger of an operation and also the in all human probability and ultimate destruction of his patient by her misplaced pregnancy. For these reasons I would advise a patient to submit to an operation at the earliest opportunity available.

Now as to the propriety of destroying a child. This question decides itself in all patients of the Roman Catholic faith. We have no right to dictate to them what should be done when it is the law of the church that no child should be sacrificed to save the mother. From a personal standpoint I would always give the mother the benefit of all chances in this murderous condition.

There are a few points I wish to lay prominently before this society: First, we have but one rupture of an extra-uterine pregnancy; the repeated hemorrhages come from a detachment of the placenta or a reopening of the old bleeding point in the tube, and not from a secondary rupture as stated in most reports of cases and by the works on the subject. The second point I wish to call your attention to is the fact that all cases that go on developing after the tubal rupture are those where the child has been forced through the tubal rent, securely encapsuled by the amniotic sac that has remained in tact, and where the placental detachment is not sufficient to destroy the life of the child for want of sufficient blood to nourish until other attachments of the placenta have been formed.

If the amniotic sac is destroyed the child is either absorbed, digested by the peritoneum or becomes encapsuled by the peritoneum in its efforts to take care of its contents when once encapsuled in this effort of nature to protect its vital organs, it may be retained for years or there may be changes in the sac or its contents that will require immediate surgical aid to prevent a fatal septic peritonitis. All the cases of extra-uterine pregnancy that go to term do so by the protective influence of the amniotic sac which has been left in tact from the start and, so far as our experience goes, is its only protection. All the cases both in my hands and those of Dr. Joseph Price have been so protected. The one operated on in Camden at the seventh month with a living child by Dr. Joseph Price was so encapsuled by the unruptured amniotic sack.

The one operated at 63rd and Woodland avenue for Dr. Weaver at the end of the second month the child was in perfect condition and encapsuled in the amniotic sack. This case would have gone on to term had not the hemorrhage been so severe as to almost destroy life. In that case I removed the placenta and tube and the child in its amniotic sack was not greatly adherent to any point save the attachments of the tube.

A person who has lead poisoning never sweats, and the mucous membrane of the intestines is as dry as the skin.

LA GRIPPE OR EPIDEMIC INFLUENZA; RESULTS AND SEQUELÆ.*

D. H. BERGEY, M. D., North Wales, Pa.

La Grippe, or epidemic influenza, is an infectious, contagious disease, characterized by the rapidity of its onset, with symptoms varying somewhat with the mucous surfaces involved, and also with the previous health of the patient, attacking all ages, though most prevalent among adults. One attack does not give immunity to a second attack, and it is extremely liable to be followed by relapses.

Bronchial and gastro-intestinal catarrh are the two forms most frequently noted, though all the mucous surfaces may be involved at the same time. The invasion is usually rapid, with initial chill or chilliness followed by considerable elevation of temperature, and prostration of unusual degree extending through the period of convalescence, which in some cases is ushered in by profuse sweating, while in others there is free perspiration during the greater portion of the course of the disease. Most cases have some headache and muscular pains involving the entire muscular system, while in some the pains partake of a rheumatic character.

As an epidemic it is remarkable for its extensive and rapid diffusion, spreading over a whole continent in a short time, and in apparent waves of varying severity of the symptoms. It is a self-limited fever, in mild cases, with the respiratory and intestinal catarrh as mere local expressions of the constitutional disease.

Etiology. It is impossible to speak definitely with regard to the etiology of this disease. While the majority of epidemics occur during the winter, but very little influence is exerted by meteorological conditions. Flint says that owing to the fact of its "being an infectious disease the germ theory offers the most rational view of its etiology."[1] Prof. H. C. Wood says—"it is undoubtedly a specific disease—in all probability the result of a specific poison—it seems to me to be imparted from man to man."[2] Dr. J. Howe Adams says—"the fact that it is in some way extremely contagious is generally accepted by the profession."[3] Dr. J. William White[4] likewise reaches the conclusion that it is contagious from the development of nineteen cases in the relatives and friends of a patient dying in Europe, in December, 1879, when the corpse was brought to Philadelphia, there being no influenza in America at that time. Dr. Edward Martin says—"from the clinical aspect the question of contagiousness seems to me as clearly demonstrated as is the contagiousness of any known disease."[5] Frey (*Deutsche Medicinische Wochenschrift*, March 10th, 1891) believes that influenza is due to a specific micro-organism."[6] Pfeiffer (*Deutsche Medicinische Wochenschrift*, January 14th, 1892), "examined thirty-one cases of influenza, and in all he found a peculiar bacillus in the bronchial secretion, in almost pure culture in uncomplicated cases. They were frequently within the pus-cells. The same bacillus were found in the peri-bronchial tissue in some cases. Control experiments show the bacilli to be absent in ordinary bronchial catarrh. The increase of the bacilli kept pace with the disease. They are small rods about the thickness of the septic bacilli of mice, but only half their length. Three or four are often joined in a chain. If great care is not taken they will be confounded with diplococci or streptococci. Inoculation experiments have been made successfully in apes and rabbits. He believes it to be the cause of influenza. Kitasato (*ibid*) made cultures of these bacilli with similar results. Canon (*ibid*) searched the blood of twenty influenza patients and found the same bacillus in all. This he thinks is the same as the one described by Pfeiffer. He did not find the organism in the blood of all influenza patients, at least those having fever."[7] Herzog (*Archiv für Kinderheilkunde*, Vol. xiv, Part 6th, 1892) believes that "one attack does not give immunity to a second attack.

All persons were liable to be attacked, no condition or age protecting against it. He believes the disease is highly contagious, and that the incubation stage is from three to six days."[8]

Symptoms. The symptoms of this disease vary much with the organs involved. The initial chill, or even the chilliness in milder cases, is followed by moderate or high fever according to the amount of systemic involvement; the headache, lumbar and muscular pains are rapidly followed by undue prostration; and the development of catarrhal irritation of either the respiratory or digestive tract, is the usual course of the milder form of cases. In the cases where the catarrhal irritation involves the bronchial tubes there is always irritating cough with copious expectoration in the later stages. As a complication in these cases we may have well-marked pneumonia developing, though more generally the disease does not progress farther than the congestive stage; or it may take the form of capillary bronchitis. The apparent lung involvement is sufficient to warrant the anticipation of pneumonia, but in robust patients it is often relieved by prompt treatment.

In cases where the catarrhal irritation involves the gastro-intestinal mucous membrane we have developed profuse diarrhœa with abdominal pains of considerable intensity. Distressing vomiting may also be present. This form of the disease frequently simulates typhoid fever but can be readily distinguished by carefully noting the temperature movement. In those cases taking the form of gastro-intestinal catarrh the symptoms may be mild and merely simulate an attack of acute indigestion, or, in the severer form, all the symptoms of a violent gastro-intestinal inflammation may be present, with severe abdominal pains, profuse vomiting and free diarrhœa. All these symptoms, however, quickly abate under the action of revulsives and other appropriate treatment.

In those cases taking the form of respiratory catarrh the symptoms may rapidly deepen into a condition of severe catarrhal pneumonia, especially in children, the aged and debilitated, and is frequently accompanied with pleuritic and pericardial involvement. The congestion of the lungs often takes on the form of crupous pneumonia, which, in robust patients, however, readily abates under appropriate treatment.

In a smaller proportion of cases the disease does not take on a distinctly catarrhal form but manifests itself by fever accompanied with severe nervous symptoms and with unusual depression. In many of these cases the heart is the most important indication of the nervous depression. In these cases we have nervous derangement ranging in severity from the mildest form of neurasthenia to those of insanity in the form of melancholia, confusional insanity, or active delirium simulating mania.[9]

Diagnosis. The diagnosis must be based on the character of the combined symptoms; on the presence of epidemic influence; on the excess of fever and other constitutional disturbance to the amount of local disease, and on the development of fever before the manifestation of the local disease; on the suddenness of the onset, and the persistence of debility during convalescence; on the marked tendency to sweating; and by the exclusion of other diseases.

Prognosis. The prognosis, in mild cases, is favorable. It is only in cases presenting organic complications, and in the very young and the old and debilitated, that an unfavorable termination is likely to result. Death usually results from some form of lung complication, nervous exhaustion or heart failure, or even all three combined. I lost three cases during the epidemic of 1891–'92; each from double pneumonia, two in aged, debilitated patients, and the other a case of organic heart disease. The exhaustive nature of the disease, with the profound disorganization of the blood, and the many complications that may possibly occur, makes this a more than usually grave disease. Even after apparent convalescence has become established there may be ultimately a fatal termination for secondary causes, more especially from consumption; but also from heart, liver and kidney diseases developing in the debilitated convalescent.

Treatment. The treatment of this disease, as a rule, does not call for active measures. Absolute rest should be en-

8 *Univ. Med. Mag.*, Vol. V, No. 5, p. 338.

9 Dr. F. X. Dercum, *Univ. Med. Mag.*, Vol. IV, No. 5, p. 369.

joyed, and all severe cases must be at once confined to bed. Camphor is claimed by some physicians to be a specific but my experience with it, though limited, does not bear out the assertion. Sinapisins, diophoretics, anodynes, quinia with supporting diet, includes all the more important measures, in the usual order, in which I found most satisfaction. The various constitutional manifestations and the different complications had to be met by the appropriate measures for which they called. For the severe headache, backache and muscular pains I invariably used the antipyretics—salicylate of sodium, acetanilid, phenacetine, and antipyrin, guarding against too large doses so as to avoid depressing the heart action. The irritating laryngitis and bronchitis were most readily subdued with free sweating, the administration of Dover's powder and the application of sinapisms, followed by ammonium chloride and quinia during the convalescing stage. The vomiting and purging in the gastric form of the disease were combated by sinapisms to the epigastrium and even over the whole abdomen, with the subnitrate of bismuth and powdered opium internally, followed by quinia after the acute trouble had passed. In the cases presenting heart weakness the use of digitalis and caffein, with strychnia, quinia and alcoholic stimulants, was generally followed by favorable results. The nervous symptoms were best met with tincture of cinchona and tincture of mux vomica, or the alkaloids strychnia and quinia. All through the disease, if the digestive tract permitted, a supporting diet was ordered, with strict injunctions against fatigue and exposure. Early exposure, or even undue exposure after considerable time had elapsed, was almost invariably followed by a relapse of a more serious nature than the primary attack, and usually with graver complications and a more prolonged convalescence.

TWO CASES OF GALL-STONES, WITH ULCERATION OF THE GALL BLADDER INTO THE INTESTINE.

JOHN M. CURRIER, M. D., Newport, Vermont.

Case I. On January 18, 1888, I was called in council to see Mr. D. L. H., affected with jaundice; aged about sixty; jeweler. He had been subject for many years to attacks of "bilious colic," accompanied with severe pains in the abdomen. These attacks were always followed by a deep jaundice. This attack was like the previous ones, but much more severe. There was deep jaundiced color of the skin and conjunctivæ; the urine heavily loaded with bile; the stools were infrequent and clay colored; nausea, loss of appetite, and several degrees of fever. This physician had diagnosed gall-stones, with obstruction in the common duct. All the symptoms became more aggravated, particularly the jaundice; and there was complete absence of bile in the stools. The patient continued to grow weaker for about three weeks. I was informed by his attending physician that he had a discharge from the bowels about that time, when the nurse heard something hard strike the bottom of the bed-pan. On examination there were found over sixty gall-stones, agglutinated into one mass by recent deposit of thick bile. They were easily separated, and were quite uniform in size, being about that of large peas. The stools were spoken of as being very offensive. They were loaded with a large amount of dark bile, and from that time on the stools contained the usual amount of bile. The patient began to improve immediately, and continued to do so though slowly, until tolerable good health was obtained. There is no doubt but that this patient had an ulceration through the coats of the gall-bladder and contiguous intestinal wall, this being a natural cure, although the function of the gall-bladder as a reservoir for bile is destroyed, and the bile would flow into the intestine as fast as formed ever afterwards. One other case illustrates the diagnosis in this one and I will relate it.

Case II. Rev. A. R. G., aged about sixty-five, had for many years occasional attacks of severe "bilious colic," which

had always been relieved in a few days, but invariably followed by jaundice. A short time would suffice to regain his usual health, although he always had a sallow complexion. His last attack had all the symptoms of the previous ones, but much more severe. His physician had given blue pill which he followed with castor oil after the case had gone on about seven or eight days. The dose of castor oil was a large one, producing much griping; the pain in the abdomen continued to increase for about twenty-four hours when the patient died. I saw the patient only after death, and made the autopsy. On opening the abdomen there was extensive peritonitis, more strongly marked over the region of the liver. There were adhesions of the gall-bladder to the intestines by recent hymph, but there was a rent of these new adhesions; allowing gall-stones to flow out into the abdominal cavity. There had been formed an opening, from ulceration, from the gall-bladder to the intestine previous to the tearing asunder of these new adhesions.

Gall-stones, too large to pass the common duct were found in the intestinal canal, in the gall-bladder and abdominal cavity.

It was decided that, had not the blue pill and castor oil been given, the patient might have recovered completely from "bilious colic" and gall stones.

These two cases illustrate the advisability of laparotomy and removal of gall stones, or the establishment of a passage into the intestines.

SOCIETY REPORTS.

GEORGIA STATE MEDICAL ASSOCIATION.

Proceedings of the Forty-Fourth Annual Meeting, held at Americus, April 19th, 20th and 21st, 1893.

FIRST DAY—MORNING SESSION.

The Association convened in the City Hall and was called to order by the President, Dr. A. A. Smith, of Hawkinsville, at 10 A. M.

Prayer was offered by the Rev. A. M. Williams.

An address of welcome was delivered by Mayor A. S. Cutts, which was responded to on behalf of the Association by Dr. Mark H. O'Daniel, of Macon.

The first paper read was the President's Annual Address, by Dr. A. A. Smith.

President Smith said that Georgia had her boards of education, her boards of trade, and her various other boards, but she had no board of health. The sanitary condition of her two million inhabitants, dwelling within the borders of 137 counties, should be looked after and cared for in an official way; and a board of health, composed of the best medical talent in the State should be established for that purpose. He knew of nothing that would be more conducive to the protection of the general health and prosperity of the people than the permanent establishment of a State Board of Health. He also recommended the permanent establishment of a State Board of Examination, and said no one should be allowed to practice medicine within the borders of the State until he shall have passed a rigid and satisfactory examination under this board, and received therefrom a certificate of proficiency. This would drive away quacks, and thereby not only protect the health and the lives of the people, but also the honor and the dignity of the profession. Furthermore, the curriculum of medical institutions in Georgia should be raised to a higher standard. Nothing less than the three course system should be tolerated, and each of these courses should be made broader, deeper, and more comprehensive. With a State Board of Health, and a State Board of Examination permanently established, and the curriculum of the Georgia medical schools raised to a higher standard, the profession would greatly accelerate the onward and upward progress of such a cause, and as it moved up onward and upward, higher and higher, mantled

with the glory of its past, and crowned with the splendor of its future, God's truth would bloom upon its brow, and God's approbation rest upon its work.

Dr. C. C. Hart, of Cross Keys, read a paper entitled "Shot-gun Prescriptions" in which he asked whether it was right to make what is known as "shot-gun" prescriptions. Personally, he thought it was not right, because it increased the difficulty of prescribing, and made the therapeutic action of medicines more uncertain and consequently less safe for the patient. We should strive to make medicine an exact science, which we could never hope to do without exact knowledge; and how are we to know what effect a certain medicine has when it is combined with several other medicines, some of them perhaps of an antagonistic nature?

Dr. J. I. Darby, of Americus, contributed a paper entitled "Puerperal Septicæmia and its Treatment."

FIRST DAY—AFTERNOON SESSION.

The first paper read was by Dr. J. M. Head, of Zebulon, entitled "Puerperal Eclampsia, with a Report of Cases."

True eclampsia might differ from epilepsy clinically, but the paroxysms of each were essentially the same. We find in eclampsia occasionally premonitory symptoms which, if properly interpreted by the obstetrician, will put him upon his guard and sometimes enable him to ward off the attack. However, in a considerable number of cases the symptoms are so slight as to escape detection, and suspicion is not aroused until severe convulsions are on. Hence we find it is of practical importance to bear well in mind the most common of the symptoms which are associated with cerebral troubles, such as severe headache, either general or unilateral, spots before the eyes, dizziness, blindness, vertigo or impairment of the intellectual facilities which are occasionally observed. Again, we see symptoms manifested in restlessness, irritability of temper, stupor, general indisposition, œdema of the cellular or subcutaneous tissue, shown by swelling of the lower extremities; but this one symptom bears with it a much more serious import when it is observed as occurring in the upper extremities or a swollen face. These symptoms are sufficient to excite the most serious apprehensions and lead us to make examinations of their causes.

So eclampsia should be considered of a functional nature through reflex influences, as chorea is an occasional feature of pregnancy. For the purpose of elucidation the speaker mentioned the prominent disorders of the pregnant stage.

"Contagiousness of Consumption." Dr. J. G. Hopkins, of Thomasville, read a paper on this subject. The speaker said he had joined the growing army which placed tuberculosis in the category of contagious diseases, and his experience with this disease during nineteen years of investigation in Thomasville—which place is a resort for consumptives—bore him out in his opinion, and made him a willing subject of the great and erudite Koch. He does not doubt but that all men, women and children at some time or times receive into their air passages, the tubercle bacilli, but fortunately the great majority possessed the power of repelling them and throwing them off—they did not find that soil, so to speak, which is adapted to their growth. Indians in a state of nature seemed impervious to the germs of consumption, but were now dying by thousands on the reservations. The whites and the blacks in prisons and asylums all over the world labored under similar conditions. A report from the Illinois State Prison at Joliet says that there are 1400 convicts within the walls, and fully one-third of them have consumption in a light or bad form. Nearly all deaths of persons in the penitentiary have been caused by consumption.

Dr. Hopkins emphasized the danger that lurks in sleeping cars, in carpets, bedding, clothing, and in the walls of apartments occupied by consumptives, which have not been properly renovated and rendered harmless by antiseptic measures.

Consumptives should be forced to provide for the destruction of sputa. Whenever situated so as not to expectorate directly into a germicide or the fire; they should use some means of conveying the sputa to the germicide or the flames. If handkerchiefs or cloths are used, they should not be sent to the laundry as human happiness and life are jeopardized through the probability of inoculation through abrasions upon the hands. These bacilli should never be allowed to dry up

and impregnate the air, as is now done through ignorance of possible result. Numerous experiments by leading medical authorities have proven beyond doubt that consumption is an inoculable disease, and so rapidly is the throng of converts growing that the speaker would not be surprised, if, even in his day, resorts now solicitating the patronage of the consumptive will be quarantining against him.

Dr. J. MacFadden Gaston, of Atlanta, read a paper entitled "Science in Medicine and Surgery."

He said at this time the medical profession was undergoing a most interesting transition from the extreme views which had been held by some in regard to the employment of germicides in surgical practice. There was a time within the past decade when it was deemed to be scientific and progressive to use antiseptic measures of the most energetic kind in all operations, whether there was a septic element to combat or not. But, thanks to the mature investigation of the effects of germicides upon normal structures by bacteriologists for this class of work, it has been demonstrated that the so-called antiseptic agents are capable of setting up septic processes in healthy tissues. The tables are now turned, and instead of a surgeon being compromised by eliminating germicides from his surgical procedures in ordinary cases, and confining his irrigation of recent wounds to simple sterilized water, it is he who departs from this course by the employment of solutions impregnated with toxic agents who is held responsible for the consequence of their absorption. In case there is a healthy and normal state of structures involved in a cutting operation, there can be no indication for antiseptics, and their use is only calculated to do harm by absorption, and the best men in the profession have ceased to employ them. The most energetic and hence the most likely to cause mischief is corrosive sublimate. Dr. Gaston quoted Dr. Vance of Louisville as saying that it was beyond all doubt that the present position of bichloride was rather against its use, and that it did more harm than good, as demonstrated by Welch and Abbott.

Dr. Mark H. O'Daniel, of Macon, read a short paper on "Multiple Neuritis, Alcoholic," and reported a case. The patient was 36 years of age, fleshy, short build, short neck, florid complexion, a bilious temperament, and a book-keeper by occupation. The patient had taken but little exercise for quite a long while except in the elbow joints. He came of a nervous ancestry, having an aunt who had died of climacteric mania and other relatives who had been insane for a short time, showing beyond doubt a predisposition on part of the patient to nervous trouble, which if it had not existed, the use of alcohol might not have precipitated the disease in question. The patient drank from one to two quarts of whiskey a day, that is during twenty-four hours. He had all the symptoms of such cases. Under appropriate treatment the patient made a good recovery.

Dr. Willis F. Westmoreland, of Atlanta, followed with a paper entitled "Syphilis from a Sociological Standpoint," in which he said year after year, particularly in the clinics, syphilitic subjects, a great many of them women, came before him suffering from this disease in all its stages, from the original lesion to the worse ravages of the second and tertiary stages, with mucous patches and syphilitic ulcers covering them. And when he found upon investigation, many of them servants, occupying various household positions as chambermaids, nurses, cooks, waitresses, etc., he could not but think that God protects the family exposed to the baneful contamination of their service, and particularly the poor little defenseless ones whom they nurse, and with whom their relations are so intimate. Any one who has not investigated the subject will be overwhelmed with surprise at the number of cases acquired otherwise than by sexual intercourse, and the various means by which it has been transmitted. Physicians and dentists are themselves exposed, and likewise expose their patients to these dangers. Thousands of physicians and midvives in the practice of their calling, in examining and operating on syphilitic subjects, or by post-mortem, are exposed. Dentists by having their fingers scratched against a rough tooth or instrument, while working on a subject whose mouth is filled with mucous patches. On the other hand, many more patients are infected by the carelessness of physicians.

SECOND DAY—MORNING SESSION.

Dr. W. H. Elliott, of Savanah, addressed the Association on "Elastic Constriction as a Hæmostatic Measure," his remarks being a review of Senn's method. He said the Association was familiar with Esmarck's method, which consisted in putting on an elastic bandage from the periphery slowly and gradually so as to empty the limb of blood, putting it on up to a point just above where the surgeon is going to operate. He then puts on a narrow elastic band at that point so as to cut off the circulation from the limb entirely, then removing the compression bandage to go on with the operation, which he had fitly called "a bloodless operation." Esmarck was not the inventor of the bloodless operation, but surgeons were indebted to his genius for improving its technique and for making this established method a popular procedure in surgery. The speaker then stated the two grave objections against the method as used by Esmarck, as advanced by Dr. Senn. The first objection was that forcible compression of blood out of the tissues by an elastic bandage was liable to send into the surrounding tissues the elements of microbic and malignant diseases. Cancer cells may thus be scattered and disseminated through the system, or the cells of pus or of tuberculosis might be sent abroad to do damage elsewhere. The second objection raised was that the constricting of the limb with a tube or a narrower bandage at one point was liable to do injury first to the muscle and secondly to the nerve. Dr. Elliott had used Esmarck's method as modified by Dr. Senn with great satisfaction.

Dr. O. H. Buford, of Cartersville, reported a rare case in obstetric practice, showing the effect of hour-glass contractions on fœtus.

Dr. W. P. Williams, of Blackshear, read a paper entitled "Persistent Remittent or so-called Typho-Malarial Fever." The author gave an analysis of a few cases of persistent remittent fever, touching its diagnosis and differential diagnosis from typhoid fever especially. He presented the clinical side of the matter, as his investigations extended no further. He presented three forms for consideration. *First*, the abortive form, or such as are immediately amenable to treatment. *Second*, the continued form with low temperature. *Third*, the continued form with high temperature. Under the first form, he was called to see the case of a negro that had been sick about a day. He found a temperature of 106°, no other striking symptom. He gave him fifteen grains of quinine, and left two other doses to be repeated at six-hour intervals. His diagnosis and prognosis were persistent remittent fever with the prospect of a long siege. He returned the next morning and found that the patient was up and gone.

The value of a diagnosis between these maladies was apparent when we came to the subject of treatment. The treatment which the speaker had followed, which had proven reasonably successful in persistent remittent fever, was the antimalarial preparation, principally cinchona and its derivatives, and arsenic, which with cholegogue cathartics (most frequently calomel) at stated intervals, applying other medicines as they were indicated. This treatment, while very beneficial in a large number of malarial cases, he would consider utterly useless and even dangerous in applying it to typhoid fever cases. The author closed his paper by saying that for every degree in rise of temperature there was a corresponding increase of heart action from eight to ten beats. In several of his cases of this fever this ratio was completely destroyed, and in some the reverse took place.

Dr. M. L. Currie, of Mt. Vernon, read a paper entitled "Periproctitis with an Abscess and Report of a Case." He said periproctitis was one of those infrequent inflammatory diseases which the general practitioner might at any time be called to treat, and which he might fail to recognize until much damage to his patient ensued. It is usually suppurative in character, but a cure may be effected by absorption even after a distinct tumor is formed. Of the cause of the disease but little can be said. It may result from traumatism, foreign bodies, extension of adjacent inflammatory processes, or any structural disease involving the mucous membrane of the rectum. The manner of its extension and the course of the morbid processes excited, are identical with those seen in perityphlitis following ty-

phlitis. The prognosis depends much upon the time when a diagnosis is made, the treatment of both the inflammation and the abscess as well as the physical condition of the patient. When the vitality is low, and the abscess high up in the pelvic cavity, or when the patient is tuberculous it is unfavorable; when otherwise, we may hope for recovery. The author then gave the diagnostic symptoms and the treatment in connection with the case he reported.

Dr. R. R. Kime, of Atlanta, followed with a paper on "Ectopic Pregnancy, its Pathology, Symptoms and Treatment." After dwelling upon the pathology and symptoms, the author summarized the treatment as follows:

1. In primary or secondary intra-peritoneal rupture of ectopic sac operate by cœliotomy at once.

2. Before primary rupture with diagnosis of tubal pregnancy extirpate cyst, tube and ovary. Fœticide for this condition by electricity and morphia injections are but temporary expedients suitable for cases of doubtful diagnosis, or where a competent operator cannot be obtained. Their use only allures patients into a false hope of security when delay is dangerous. If diagnosis could be made in the first three or four weeks of pregnancy then electricity might accomplish more potent results.

3. With extra-peritoneal primary rupture into broad ligament in early weeks of gestation producing pelvic hematocele, wait for absorption of effused blood; if it fail, then perform cœliotomy or vaginal drainage.

4. If child survives primary rupture of tube into broad ligament, do not commit murder, keep a clean conscience toward God and man, let fœtus live, keeping patient under strict observance ready to operate at any time when life of patient demands it, or fœtus has at least reached a viable period. By waiting for development of fœtus and cyst as Tait claims, the peritoneum is pushed up on the side in which they are located, so that in later months of pregnancy a lateral incision will enter cyst, and fœtus may be extracted without entering abdominal cavity.

5. Surgical interference should be the rule in all cases of ectopic pregnancy reaching full term even after spurious labor and death of fœtus.

Dr. Luther B. Grandy, of Atlanta, read a paper entitled "A Board of Medical Examiners; the State's Medical Duty," in which he suggested, in November last, the advisability of taking steps toward the establishment of a board of medical examers in Georgia. The question under discussion was one which touched every home in Georgia, into which sickness or accident would surely come at one time or another. There were two classes of so-called doctors from whom the people of this and every State need to be protected. One was the ignorant practitioner without capacity, the other was the unprincipled charlatan without conscience. The absence of such a board and the fact that a diploma was a license was but throwing down the bars to all the incompetent and fraudulent who were being rejected in other places. And here was the point of the matter which was of the most interest to physicians, because it had such a bearing upon the *personnel* of the profession of the State. If the medical profession in Georgia was to be made up largely of those who had been refused by other States on account of incompetency or dishonesty, then it was time we were entering our protest at once. There were about 2,700 physicians in Georgia, and still they came, and all were welcome. None were ever rejected. By a reasonable estimate about 700 of these would have been declared unqualified in other States. There had been nearly 400 rejections by the Virginia and North Carolina boards within the last seven years. What became of all those persons who were examined and declined by the boards of New Jersey, Virginia, North Carolina, Florida, Alabama, Illinois, Minnesota and other States? Our neighbors, Alabama, South Carolina and Florida, have rejected respectively 20, 29 and 30 per cent. of their applicants. Where do these people go? As for the quacks, when driven from one place they quickly take refuge in another. They change their sky but not their affections (*Cœlum, non animum, mutant*). Like other moving bodies they travel along the lines of least resistance until they find some place still willing to receive and patronize them. Dr. Grandy closed by saying that if Georgia would like to divorce the right to practice medicine from the empty honor of having a diploma; if she would like to bring about

higher standards in her medical schools and stimulate her students to higher aims; if she would like to improve the *personnel* of the medical profession in the State and endeavor to make it what it should be, an intelligent, honest and conscientious body of physicians; then let there be established a Board of Medical Examiners who shall be untrammeled of any college connections, and who shall determine whether a given applicant is qualified to practice medicine in Georgia.

Dr. Arthur C. Blain, of Macon, contributed a paper entitled "The Practice of Medicine in Georgia." He called attention to the want of laws governing the practice of medicine in the State. He also emphasized the importance of creating a State Board of Medical Examiners. Georgia was made a dumping-ground for all who failed to pass the requisite examination to obtain a license to practice in Virginia, Florida or Alabama. State Boards not only afforded protection to the people from charlatans and unqualified practitioners, but exerted a salutary influence towards elevating the educational standard of the medical profession. The speaker recommended that a committee be sent to Atlanta during the next session of the legislature to assist in formulating and passing some good law that would meet the requirements of the case.

Dr. J. C. Avery, of Atlanta, followed with a paper on "State and Municipal Hygiene."

The three papers were ably discussed by Drs. C. D. Hurt, R. O. Engram, Willis F. Westmoreland, W. H. Elliott, F. W. McRae, M. B. Hutchins, and a committee of one from each congressional district appointed for the purpose previously outlined.

SECOND DAY—AFTERNOON SESSION.

Dr. C. D. Hurt, of Atlanta, read a paper entitled "Etiology of Puerperal Eclampsia; its treatment, with report of some Typical Cases." After a careful study of various authors and summing up his observations and experience at the bedside, the author felt warranted in offering the following conclusions: (1) That eclampsia gravidarium in every case is the result of some influence which is directly or indirectly exerted upon the nervous system causing a derangement of its functions. (2) That such influences may exist singly or be cooperative, and that such influence may be direct violence or mechanical pressure. (3) That one or more of these influences may reach the nervous system by absorption or through the circulation. (4) That by chemical changes wrought under certain conditions in the system, toxic elements may be created and proved deleterious. Again, certain elements are harmless as they exist in normal proportions in the constitutions, but exert a toxic influence in abnormal quantities. Urea as a toxic element abnormally increased by retention in the system is assigned by many as the most frequent cause. Yet there are some who do not hold to this opinion. All admit that eclampsia and uræmia coexist in a very large per cent. of cases, while they disagree as to their relation of cause and effect. Furthermore, all admit that uræmia cannot be found to exist in every case of eclampsia, therefore, other causes than uræmia can and do produce eclampsia. That in every case irritation may and does exert an influence which materially aids in bringing on a seizure, and that in many cases this irritation intensified by protracted labor, hard pains, unyielding os and exhaustion of the nervous system develops eclampsia. That a plethoric condition of the patient, full habit, distended blood vessels, increased susceptibility to an apoplectic condition and excessive irritability, and that with this plethora a crowding of the blood into the lungs and upon the brain materially interfere with the functions of the nervous system. That the emotional system is not silent in some women, and that it helps to precipitate the fit.

Dr. H. McHatton, of Macon, read a paper entitled "Four Women who Refused Oophorectomy and their Subsequent Histories." The author gave a brief resume of the histories of the only four women that he had ever known who refused the operation. The time that had elapsed since it was advised varied from eighteen months to twelve years. The speaker made the point that in each case the operation was advised and urgedby gynecologists of standing both North and South; consequently they must have been convinced that they were cases demanding operative interference. In a practice of twelve years he had had occasion to rec-

ommend the removal of the appendages once, excepting cases of ovarian tumors, and that one proved to be a case of pyosalpinx. Several of his patients had drifted into other hands and had oophorectomy performed, and as far as he could learn had been disappointed in the results each time. The best men in this special line of work were doing the operation less and less each year. Their place was being amply filled by lesser lights, with smaller numbers of individual cases, but with a yearly aggregate that is terrible to contemplate. By what combination of circumstances could one man, to fame unknown, in a small interior city, and in a short space of time, find 144 cases demanding abdominal attention?

Dr. C. H. Peete, of Macon, contributed a paper on "Partial Tenotomy, A Radical Cure for Heterophoralgia." The author finds that the majority of cases suffering from heterophoralgia are those of young adult life, or that they have been sufferers since that time. He accounts for it by the fact that we know in order to cause it the patient must concentrate his vision on an object, and the length of time of this concentration governs the intensity of suffering. In children the vision is never fixed on any part for a length of time, consequently the symptoms are not brought on. In young adults, who have acquired the habit of hard study and constant close work, it occurs frequently, and we will find in most cases that it commenced with the time of their beginning to work or a short time after. The muscle tests should be applied to every case that came to the occulist for refraction work, and when he finds these deviations existing he should resort to the radical relief, partial tenotomy.

Dr. F. W. McRae, of Atlanta, read a paper entitled "Stone in the Bladder, with Report of Cases." He dealt with the etiology, symptomatology and treatment of stone in the bladder, purposely avoiding extensive details and references to authorities. The chief predisposing causes were defective digestion and assimilation, due either to improper diet, to a preponderance of solid over liquid ingesta, or too high living coupled with insufficient exercise and imperfect oxidation. There is an excess of the solids of the urine. These are only predisposing causes and others such as mucous, pus, etc., due to inflammatory conditions of the urinary mucous membrane, must be present before stone in the bladder will result. A history of nephritic colic not followed by the expulsion of the gravel through the urethra would naturally lead us to suspect the formation of stone in the bladder when followed by irritation of that viscus. Only when the stone can be felt by the searcher and the characteristic click elicited are we sure of the presence of calculus in the bladder. In one of the cases which the author reported the symptoms were characteristic of stone in the bladder, although no stone was found. The operation was a brilliant success in relieving the patient of a most violent cystitis of long standing. The author then dealt with the methods of treating stone in the bladder and said that no method had so wide a range of applicability and as low a death rate as litholapaxy (Bigelow's operation). He had, however, no personal experience with it, as the cases thus far presenting themselves to him were such as might be best treated by other procedures. This operation offered much the best results except in very young children, very large or very hard stones, or where there was co-existing tight organic strictures or enlarged prostate of such character as to prevent the introduction of the lithotrite, or where there was a violent cystitis associated with stone. For large stones associated with prostatic or vesical tumors the high operation was undoubtedly far superior to the perineal operations. Small stones associated with stricture of the deep urethra or violent cystitis were best treated by the median operation. Nor was the lateral operation to be entirely set aside for the now more popular operations of litholapaxy and supra-pubic lithotomy. Each of these operations had its proper field of usefulness, and it was only by a careful selection of the methods of treatment that the best results were to be obtained.

Dr. W. R. Googe, of Abbeville, reported a case of fracture of the skull with protrusion of the brain substance and removal of same.

THIRD DAY—MORNING SESSION

Dr. J. B. Holmes, of Rome, read a lengthy paper on "The Technique and After-Treatment of Ovariotomy." The

author offered the paper as an *expose* of the methods adopted and successfully used by him in his abdominal work. He submitted the paper with the earnest hope that it might elicit a full and free discussion from all who might be interested in this line of work. By such discussions our methods may be compared and those adopted that promise best results to our patients. No one could truthfully say that in every particular his method was the best. While we might in the main agree, yet on slight and seemingly indifferent details might hinge the successful issue of our cases. He stood ready and willing to take any suggestions from his brother surgeons if he could get better results by so doing. The author then took up each step *seriatum* of the technique and after-treatment,

Dr. Frank M. Ridley of La Grange, then delivered the Orator's Address. He selected for his subject "Woman's Relations to the Practice of Medicine."

Dr. M. B. Hutchins, of Atlanta, contributed a paper entitled "Mechanical Treatment of Some Skin Anomalies." The author dwelt upon some of the various mechanical means of removing anomalies of the skin. The destruction of superfluous hairs, of moles, birth-marks, and the various simple growths of the skin were described. In 1879, Dr. Michel, of St Louis, successfully employed electrolysis for the destruction of hairs in trichiasis. Dr. Hardaway, a dermatologist of the same city, followed the idea in the tratment of hypertrichosis. Various dermatologists had since reported upon its successful use. Hair upon the lip and face of women afforded the usual field of operation. Three to eight cells of a galvanic battery were used. For the past two years Dr. Hutchins had used some "Law" cells put together by himself, containing as the fluid an aqueous solution of sal ammoniac. For the destruction of hairs five of these were sufficient, though they had not been filled in two years. Seven of these cells sufficed for ordinary moles. To the negative pole a pencil-shaped needle holder containing a number eight or twelve sewing needle is attached, while the positive pole is provided with the usual sponge electrode. The needle is attached to the negative pole for the reason that electrolysis through the positive will leave a black dot at the point of insertion of the needle. The author prefers the needle holder having a spring for opening or closing the circuit, as this leaves the entire control of the circuit to him, the patient steadily holding the well-wetted sponge electrode in one hand instead of having to open and close the circuit by letting go or catching hold of the sponge. The needle is carefully inserted into the hair follicle, parallel to the root, until slight resistance, the bottom of the follicle and the seat of the hair papilla is felt. The circuit is then closed and the current allowed to pass until a frothy substance the size of a small pin head fills the follicle, and a small area of blanching appears around the needle. If the needle has followed the course of the hair root and remained in the follicle, the pain is less than when the root sheaths are pierced, and the frothy substance is more abundant. If the hair is easily pulled out it is reasonably certain that there will be no regrowth, but if it pulls out with difficulty or breaks off, the current must immediately be reapplied. A pair of forceps made for the purpose are used to extract the hairs.

Dr. Hutchins then reported several interesting cases which he had treated successfully by electrolysis.

The following officers were elected:
President, Dr. W. H. Elliott, Savannah.
First Vice-President, Dr. G. T. Miller, Americus.
Second Vice-President, Dr. H. McHatton, Macon.
Secretary, Dr. Dan. H. Howell, Atlanta.
Treasurer, Dr. E. C. Goodrich, Augusta.

The next Annual Meeting of the Association will be held in Atlanta.

A Georgia Editor Wants His Money.

The following is from the pen of a Georgia editor who evidently had strong feelings on the subject: "The wind bloweth, the water floweth, the farmer soweth, and the subscriber oweth, and the Lord knoweth that we are in need of our dues. So come a-runnin' ere we go a-gunnin'; we're not funnin'; this thing of dunnin' gives us the blues."—*Ex.*

In measles, when the temperature is high after the eruption has faded, there are complications.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 - 18 - 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 20TH, 1893.

EDITORIAL.

MEDICAL LEGISLATION IN GEORGIA.

Dr. Grandy has been untiring in his efforts to secure a higher medical standard especially in his own state, and under his direction the *Atlanta Medical and Surgical Journal* has exercised a powerful influence towards securing legislation to this end.

The current number of his journal contains a paper recently read before the Georgia Medical Association presenting the situation as it now obtains. The bill for the establishment of a Board of Medical Examiners in Georgia, after encountering rabid opposition from sources common all over the United States, passed the Senate by a nearly four-fifths majority but got tied up in the Committee of the House so that further action was postponed until the next meeting of the Legislature. Thus the bill may be considered as still pending. This ought to be encouraging to the gentlemen interested. They commenced operations last November and it would be miraculous to have enlightened an ordinary legislature on this subject in so short a period. Had the present set back been absolute it would only have delayed victory, for accept defeat these advocates of progress could not if they would. To give up is not a characteristic of the species.

Dr. Grandy's trenchant statements are made in plain words. Some of the comments are of more than local application, and the REPORTER presents them for the benefit of every friend of medical progress.

"There are two classes of so-called doctors from whom the people of this and every State need to be protected. One is the ignorant practitioner without capacity, the other is the unprincipled charlatan without conscience. A large proportion of the citizens of any State have not intelligence enough to protect themselves against these persons. Then it becomes the duty of the State to protect them. If those who offer their professional services to the community were everywhere what they should be, both in intelligence

and integrity, there would be no cause for legislation. But the disagreeable fact remains that the medical schools of the country every year send out young men totally unqualified for practice, while there are those so devoid of every sentiment of honor that they are willing to extract their dishonest livelihood by preying upon the ignorance and credulity of those whom they are able to deceive."

"The mistake which underlies the present law, if it may in charity be called a law, is in giving to a college diploma the authority of a license. This is indeed the *fons et origo mali*. In giving too much power to colleges, actuated as they may be and often are, by personal interests, to make them the judges as to the qualifications of those who wish to practice medicine. The mission of the college is to *teach* the student; to *license* him to practice is quite a separate and distinct duty belonging to a separate and distinct power. The President of Harvard University has said: 'Why is it that admission to the profession of medicine (in Massachusetts) is at a disadvantage as compared with admission to the profession of law? The very last thing the law school or the law faculty would desire would be that their degree would admit to the bar. It is a clear disadvantage in medical education that the degree given by a faculty, a teaching faculty, should admit to the profession. The standard should always be outside, determined by another power."

"The United States is the only country in the world in which this blunder is allowed. A diploma is no guarantee of professional fitness. The value and significance of a bare diploma are diminished now by the commercial spirit which plays too important a rôle in our teaching institutions Our law-makers may not know it, but it is a fact that there are too many teachers in our faculties everywhere who appear to believe that the success of their teaching plant is proportional to the amount of money that may be gotten out of it. It is this spirit which graduates students every year and declares them competent to practice a responsible profession who ought to be sawing wood or making brick."

"The medical degree can be too easily and cheaply gotten in this country. Did you know that there are places where a diploma may be bought for a mere song, and no questions asked? A New York *Herald* reporter recently bought the title "Doctor of Medicine" from one of these for fifty dollars. There are two hundred and twenty-five "graduates" of these bogus institutions practicing medicine *upon their diplomas* in Pennsylvania. For this sort of "doctor," so-called, conceived in sin and born in iniquity, an honorable people and an honorable profession can have nothing but contempt. I do not know if there is any of this unlawfully-begotten species in Georgia; but there may be, *and his diploma is his license.*"

"One of the most important and salutary results of this sort of legislation is its effect upon medical education. The existence of so many of these examining boards in the States has been one of the most potent factors in arousing the colleges of the country to better work. The latter know and appreciate that the character and thoroughness of their teachings will be measured by the fitness or unfitness of their graduates as determined by these examinations. The consequence has been that our system of medical education has been overhauled and improved within the last five years as never before."

"In medical education the proper solution lies in the application of the Malthusian principle: "Fewer conceptions and a prolonged period of gestation." As it is, we are having a premature delivery of young doctors every Spring. They come—

> Deformed, unfinished, sent before their time
> Into this (medical) world, scarce half made up,

and there is nothing to stand between them and the people among whom they choose to locate."

"In the hands of such persons the lives of the people are not safe, and there is properly no place for them in the profession.

In Pennsylvania it has taken years of patient, arduous effort to distract our legislators from their occupation of saving the country long enough to allow common sense an opportunity to exercise itself in medical matters of importance to the public. Just now success seems certain. The Medical Examiners' Bill, as outlined in the REPORTER, has been passed by both branches of the Legislature, and is in the Governor's hands. It will hardly fail to meet his approval.

FORTIFIED AGAINST MICROBES.

It is currently reported that the Faculty of Medicine, at Madrid, has established an antiseptic operating theatre on a principle entirely novel—and equally absurd—which, according to the *Medical Press*, has received the label, "Quirofano," which is being interpreted "transparent surgery." Those lively disease germs, whose activity and cunning have circumvented all measures hitherto devised to prevent their preying on humanity, are not only to be excluded from their victims, but are to have their disappointment deepened by viewing through impermeable glass the opportunities no longer theirs.

The patient, the surgeon, his assistants, all instruments, in fact everything connected with the operation is to be intrenched within a veritable wall of glass. Thus, the patient will be kept absolutely isolated. Spectators can witness all details of the work, likewise they can hear the remarks of the operator, we presume by telephone attachment.

This is trancendental antisepticism as well as unmitigated nonsense.

The festive microbe will continue to use his ordinary means of approach, *i. e.*, the finger nails, hands, clothing and person of the operator and his asssistants who believe that the free use of antiseptic solution absolves them from an assiduous and most pains-taking effort to secure personal cleanliness by exhibition of hot water, soap and scrubbing brush.

TRANSLATIONS.

Icterus and Acute Atrophy of the Liver following Syphilis.*

H. Senator says that early manifestations of disease in the liver and uterus, accompanying syphilis are almost unknown in Germany, while they are often observed in France. The jaundice runs a course of an ordinary catarrhal form if treated specifically. The observations of Engel-Reimer's of Germany agree fully with those of the French.

Senator has had no cases under his own observation but is a firm believer in specific jaundice. Its origin is explained in various ways.

Gubler thinks it analogous to that of the exanthema. Cornil and Lanceran explain its origin by the fact of glandular swellings in the portal hepaticus. Engel-Reimers is of the same opinion. Senator is inclined to favor Gubler's views and believes it to be due to inflammatory swelling of the intestinal mucous membrane.

Of greater importance is the appearance of atrophy of the liver following syphilis. Engel-Reimers saw three cases; Senator

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

observes two cases of characteristic atrophy of the liver.

One case has been thoroughly cured in spite of grave inter-current diseases. The diagnosis is, nevertheless, indisputable, since there are other cases on record of cures in acute atrophy of the liver, for instance those of Leure. With these two cases of Senator's there exist in the literature only nine cases of this affection following early infection of syphilis; namely, two men and seven women. Mercurial poisoning can be excluded with safety.

In discussion Fleischauer reports a case in which an autopsy disclosed a large gumma in the liver and great swelling of the portal glands, following a case of icterus in early stages of syphilitic infection.

Bauer saw a case of recovery from atrophy of the liver which died three months later from miliary tuberculosis; the autopsy showed complete nerve function of the liver.

Quincke has had occasion to observe three or four cases of early syphilitic icterus; there were a few gastric symptoms. He is inclined to believe in the theory of compression of the Ductus Choledochus by swollen glands.—Extract from Twelfth Congress f. Med. Wiesbaden. *Deutsche Med. Zeit.*, 24–93.

Treatment of Drunkeness with Strychnia.*

Dr. Kellerman, reports a case of a widow, age 66, who has been a drunkard for sixteen years. During one of her sprees she sustained a fracture of the clavicle, and during the treatment of this, the strychnia injections were used. The patient's general health was below par, and for that reason only small doses of strychnia were at first administered. The solution of strychnin nitr. 0.02 to 10.0, of this solution ¼ gram was injected subcutaneously and increased after a pause of three (3) days to ½ gram.

The patient was told that these injections were solely given as a tonic. The patient, however, complained of increased restlessness, sleeplessness, drawing pains in the limbs, etc. After the fourth (4) injection she forbade any further injection. It was noticed that after the first two (2) injections, she still took small quantities of whiskey, but later seemed to have given up.

She has not been drunk within the last thirteen months, since the treatment, her strength has increased, she is again doing light work and insists that whiskey has lost its good taste and is deteriorating in its good qualities.—*Aerztl. Mittheil. Aus. w. f. Baden.*

Clinical Contributions on the Subject of Intestinal Occlusion.*

The author's (Prof. Hofmokl) contributions, based as they are upon personal experience, are of considerable value to the profession. The position taken regarding time and kind of operation, is first, radical operation as early as the diagnosis is definitely made, the results being in favor of "too early" rather than "too late" surgical interference; and second, that each patient should have the benefit of a doubt.

Forty-four (44) cases with their clinical histories in detail, which contain numerous points of interest, and are well worthy of careful study.

The classification of the cases operated on are as follows:

Group	Classification	No. of Cases	Kind of Operation	Recov.	Imp.	Death
1	Koprostase	1	Laparotomy	1		
2	Neoplasm					
	(a) Small Intestine	3	Resection	3		
	(b) Cœcum and Ascending Colon	6	"	3		3
	(c) Sigmoid Flexure.	2	Anus preternaturalis		1	1
	(d) Rectum	2	Resection—Method of Kraske	1	1	
	(e) Vagina and Uterus	2	Anus preternaturalis		1	1
	(f) Peritoneum and Omentum	1	" " "			1
3	Cicatrical Stricture of the Small Intestine	1	Resection of Ileum and Cœcum	1		
4	Vermiform Appendix	4	Incision Laparotomy with Resection of the Intestines	1		3
5	Intra Abdominal Strangulation	8	Laparotomy	2		6
6	Gangrenous and Strangulated Hernia	9	Anus preternaturalis—Resection of the Intestines	6		3
7	Traumatic tear of a portion of the Intestines	1	Laparotomy			1
8	Occlusion of the Intestines—cause unknown	4	Anus preternaturalis—Laporatomy		1	3
	Total	44		18	4	22

In studying the results (50 per cent. mortality) we must remember that twelve cases were almost hopeless at the time of operation — *Klin. Zeib-und Streitsragen* Bd. IV., 1892.

ABSTRACTS.

PRACTICAL HINTS REGARDING THE ADMINISTRATION OF MEDICINES OR APPLICATION OF REMEDIES.

LEROY M. YALE, M. D., New York City.

The giving of medicines often requires a little tact, and a knowledge of details helps exceedingly to the successful administration. Before entering upon these details, a few general remarks may be made.

First of all we would deprecate the practice often indulged in by the ignorant, and sometimes by those who should know better, of holding up the physician as a bugaboo and the administration of medicine as punishment, or, at the least, a thing to be dreaded. Medicines sometimes are unpleasant, more commonly need not be, and in any case it is the part of wisdom to prepare the way for a possible need by speaking of remedies as helpful rather than as objectionable, and of the physician as a family friend in time of need rather than as a beadle or nursery executioner.

Another general suggestion is this: Do not make a parade or fuss in getting your remedy ready. If anything of the sort be necessary, let it be done out of the child's sight and the remedy be brought when ready for administration; it may then be swallowed without objection, while, if time had been allowed, antagonism would have been excited. Make the giving of each dose as tidy as possible.

If doses are to be given frequently, or for some time, it is of help to make out on a slip of paper a schedule of hours for them, and as each dose is given, draw a line through that hour. This shows, afterwards, not only when the dose should have been given, but that it was given. The plan is especially useful to avoid confusion when more than one remedy is required.

LIQUID MEDICINES.

Liquids constitute the chief form of medicine given to children, owing to their inability, as a rule, to take other forms. If a medicine has little taste, or at least little disagreeable taste, this form is unobjectionable, but otherwise the other forms are preferable as soon as the child is old enough to take them, as in them taste can in one way or another be hidden. Medicines are sometimes insoluble and must be given in some more solid form. It should be remembered that some infants dislike to take anything into the mouth except by sucking. It is rather hard to teach such children to take even a drink of water from a cup or from a spoon. The giving of water even to the youngest suckling is always to be recommended, and it is an additional reason for so doing that by this means the child learns to take liquids from a spoon or cup, and has less difficulty in taking medicine in case an emergency arises. If a medicine is prescribed by a physician, learn from him just how it is to be given, even as to the amount of water in which each dose is to be administered. This latter point may not be important in many cases, but in another it may. For instance, saline medicines largely diluted may act upon the kidneys, while, if less diluted, they would more probably act upon the bowels.

As a rule, medicines which are in any degree pungent or which might be irritating, should be largely diluted, or water be given directly afterward. On the other hand, medicines which have a decided taste should be diluted as little as is consistent with the foregoing rule, in order that the disagreeable taste may not be unduly prolonged. It is not good policy to sweeten such medicines, but rather to give the *douceur*, whether a sweet or a tasty fruit, immediately afterward. Sometimes a decided taste, as of orange juice, in the mouth just before the medicine, is an excellent disguise, especially if it be repeated just afterward. We will speak of this more fully presently.

If a liquid is to be given in doses of a certain number of drops, especially if given frequently, much time and annoyance may be saved by mixing a number of

doses at once. For instance, suppose the physician has ordered that a drop of tincture of aconite be given every hour or half hour until certain effects are produced. The dropping a single drop thus often is sometimes difficult, especially with the agitating circumstances which attend a baby's illness. It is then better to drop into a tumbler or some other convenient vessel a certain number of drops of the medicine, it does not much matter just how many, if they be counted. Then add the same number of teaspoonfuls of water, and mix thoroughly by stirring. Evidently each teaspoonful will contain one drop of the aconite, and it is only necessary to stir the mixture well before each dose and to take up the teaspoonful, to ensure the proper quantity. If the dose were larger, it is easily gotten at by giving the requisite number of teaspoonfuls; or, if smaller, by adding a proportionately larger number of spoonfuls of water at the start. In any case drop the medicine before adding the water.

In spite of the advances of pharmaceutical chemistry it is sometimes necessary to give solutions containing acids either as such, or as helping the solution, like some preparations of iron. These solutions "set the teeth on edge," and fears are naturally entertained, and sometimes with reason, lest the teeth be injured. In such cases it is well, unless the physician has a reason to the contrary, to resort to the following device to prevent harm. Before giving the dose, dissolve a little baking soda, say, a good pinch, in a third of a tumbler of water, warm water we prefer. As soon as the acid dose is taken, let the patient rinse the mouth with the soda, which neutralizes the acid and removes the "on edge" feeling. If the child is too young to do this, wash the mouth with a rag dipped in the soda. Older children can also prevent harm to teeth by the use of a tube or straw in taking the acid.

Oily liquids require some special attention. In domestic practice, and on the whole wisely, castor oil plays an important rôle. The fact that this remedy keeps its place in spite of its well-known inconveniences is evidence of its usefulness. But its giving need not be made so difficult as it often is. If the oil is fresh and of good quality, its taste is not nearly so bad as that of many things more readily taken. If through carelessness the oil becomes rancid, it is a nauseous dose. Oils exposed to the air, especially in warm places, easily undergo changes, and the following precautions should be observed as regards castor oil, cod liver oil, emulsions of either, or of almond oil, often used in cough mixtures. Keep always in as cool a place as practicable. Before giving a dose, see that the neck of the bottle is clean on the outside. Pour out the dose carefully and clean the stopper and neck inside and out before the former is replaced; then cork tightly. The reason of this is that if a film of oil is left exposed to the air, it soon becomes rancid, and in pouring the next dose some of the rancid oil goes with it—enough to give a taste; and when the pouring ceases, the oil that returns to the bottle carries with it some of the rancid oil, enough often to set up a similar process in the bottle. Similar precautions are useful, but not so necessary, for syrups or thick solutions containing gum or sugar.

In administering oils (and we may take the castor oil as a type) it should be remembered that a good deal of the objectionableness is due to the viscidity. Therefore, first heat the spoon by immersion in hot water, or in any other way. If the child is old enough to be allowed, or to have acquired a liking for, sapid things, it is well to squeeze a little orange juice into the hot spoon, then pour in the oil and squeeze a little more juice over the oil. The heat of the spoon makes the oil flow more readily, and the juice above and below renders the oil hardly recognizable. If the baby is so young as to object to the spoon *per se*, there is no use in trying to disguise the oil, but this heating of the oil or spoon is always helpful.

This is a proper place to say that we believe that much of the disgust manifested by children for medicines is simply imitation of their attendants. When, many years ago, we were told by an old physician that children rarely objected to cod liver oil unless they had seen their elders make a face at it, we were surprised, but experience has convinced us of the correctness of the statement. So far as we have observed, more children actually like cod liver oil emulsions, for instance, than object to them.

MEDICINES IN SOLID FORM.

To little children, powders, pills, capsules and tablets are often more difficult to administer than any liquid. This is frequently so because to them swallowing has been an automatic act, and when they endeavor to swallow, even with the best intent, a small object, it is likely to lodge in some part of the mouth over which the child has little control. This, and not the covering of the taste, is the secret of the success of the old-fashioned device of hiding the pill or powder in a good-sized crumb of bread. A large and sufficiently soft bolus is thus formed which the tongue can readily manage. The draft of water acts in the same way. It can be swallowed, and with it goes the dose. This also is one of the advantages of the wafer paper used in administering medicines. Common thin white tissue paper will serve to hide a bitter powder if no better cover is at hand. It may then be taken as a pill, placed well back on the tongue and swallowed immediately with a full draft of water.

There are one or two points about the physiology of swallowing which, if understood, are helpful, namely, first, that swallowing is made easy by the action of the saliva moistening the mass to be swallowed; but if, to avoid taste, speedy swallowing without time being allowed for insalvation be required, or if by reason of fever the mouth be dry, swallowing will be more than usually difficult. Hence another reason for the drink of water. Secondly, that while the passing of the bolus to be swallowed through the mouth proper is done by the muscles of the tongue, which are voluntary muscles even if they act unconsciously, when the bolus reaches as far back as the uvula, it comes within the domain of muscles which act spasmodically and force it down the throat. Every child knows that if it allows a candy to get too far back on the tongue, it "slips down the throat." Hence, if by reason of nervousness or of anything else a pill cannot be swallowed, it is only necessary to place it upon the back of the tongue, and it must go. If there is left a sensation that it has "stuck" anywhere, a draft of water will remove it.

POULTICES.

The making and application of poultices requires a little knack or knowledge. The materials used may be various, but a few kinds only are in very common use, such as freshly ground flaxseed, ground slippery-elm bark, and bread and milk. Whatever is used, the mixture must be, when done, entirely smooth; nothing hard or harsh is admissible. If bread and milk or bread and water be the materials, the boiling water should first be poured into a hot bowl, or the water may be heated in a saucepan. In either case the bread-crumb, no crust, should be broken into it and the whole beaten together with a fork, to keep the mass as light and soft as possible. Flaxseed meal or ground elm bark may be stirred into the hot water and heated till the mass boils or steams and becomes soft. A poultice should not be so stiff as to be harsh, nor so thin as to run.

Any soft, thin fabric of sufficient strength will do for a poultice cloth. Of late years the porous materials known as cheese cloth and butter cloth have in great degree displaced others. They are very suitable to the purpose and so very cheap that they may be thrown away without thought. Bags of these materials of suitable size may be made, into which the poultice mass is filled when ready and the open side stitched up, or a suitable piece of the stuff may be laid upon a hot plate and the mass spread a ½ inch thick or more, the edges turned over and stitched together if they do not remain in place without. The poultice should be always large enough to considerably more than cover the surface to be acted upon; a boil, for instance, having a reddened surface 2½ inches across, will require a poultice 4 inches square at least.

One of the inconveniences of poultices is their drying and sticking to sensitive surfaces or to parts upon which short hairs grow. This may to a great degree be obviated by first putting oil or vaseline upon the surface of the skin or of the poultice; and both the drying and cooling may be hindered by placing over the poultice a piece of oiled silk or gutta-percha tissue, and over it again some cotton batting, the whole to be kept in place by a bandage or the like. The older method of making poultices covered on one surface only with cloth favored this sticking, but the open-textured kinds of poultice cloth mentioned may cover both surfaces of the poultice mass, one lying between the latter and the skin.

In putting on a poultice let it approach the surface to which it is to be applied gradually and put it in place as soon as the heat can be borne. It usually needs renewal in a few hours—two to four on an average.

In the absence of any suitable poultice material a temporary substitute may be found in a thick piece of cotton batting, or, still better, absorbent cotton, dipped in hot water, pressed partly dry, and applied and treated, as to covers, as advised for a poultice.—*The Mother's Nursery Guide.*

GRAFTING WITH PIGEON-SKIN.

Being called upon to attend those injured in neighboring mills, on some of whom it became necessary to do skin-grafting, and the want of a more easy method of performing the operation, says Dr. Aldrich, suggested to me that I had better try the grafting of granulating surfaces with squab-skin.

The Thiersch method of grafting has one drawback, or at least one feature that makes it appear like quite an operation to the patient and his friends, and that is the giving of an anæsthetic in order to take the grafts from the patient or some one else. The taking of human skin probably adds to the brilliancy of the operation when considered by the laity; whereas this method of pigeon-skin grafting suggests little more to the patient than an ordinary dressing does.

In my first attempt at pigeon-skin grafting I selected a pair of young squabs that were of an age when the feathers had not yet shown themselves along the under surface and under the wings. I removed the featherless skin and placed it on a healthy granulating surface, which had previously been cleansed with a four per cent. boracic acid solution. The result of this first operation was fairly satisfactory. Since this first pigeon-skin grafting I have grafted a few times.

The last time I grafted a granulating surface the operation was as successful as any one could wish. I proceeded as follows: Having killed two squabs that were about half grown, I immersed them in warm boracic-acid solution and quickly plucked the feathers; then immersing them in a clean boracic solution, I proceeded to scrub them. My next step was to skin them, removing large pieces at a time, which were immediately placed in warm sterilized water. The granulating surface having been thoroughly cleansed with boracic solution, and then with warm sterilized water, the grafts were placed upon it. Over the grafts gutta-percha tissue was placed, and then warm compresses wrung out in warm boracic solution; over these a layer of dry cotton, and then the bandage.

In my former operations the pus and the liquefied grafts had floated many good grafts and prevented their "taking." I therefore concluded to change the dressings earlier than I ever had before. About forty hours after the operation the dressings were removed, the pus and melted pigeon-skin mopped away with wet compresses; the grafts that were not melted were left in place, and over the surface was applied plain gauze with a layer of resin ointment spread on it, over this borated cotton and then the bandage.

At the end of the next forty-eight hours it was dressed again in the same way, and at the end of the following forty-eight hours it was dressed again. Since this dressing it has been dressed every third or fourth day either with boracic vaseline or resin ointment.

Observations.—Do the grafts grow by a reproduction of their own elements, or do they simply stimulate the granulations, and cause them or the tissues underneath them to take on an epithelial growth?

In one case that I grafted the surface had been stripped by cogs. In the upper part of this lacerated area was a small island of skin that was not removed, but which in time became completely lost sight of, on account of the granulations having swallowed it up, so to speak; yet, later, this same skin came to the surface, and its edges finally coalesced with the skin at the margin of the wound and also with the grafts which had "taken," in close proximity to it. The swallowing

of this island seems to me to be analogous to the swallowing of the epithelial cells, which later only spring to the surface just as this island did.

The success of this method of grafting in my hands appears to me to be equal to the success of the auto-epidermic-Thiersch method. Pigeon-skin grafting does not necessitate an anæsthetic; its failure does not discourage because squabs are as cheap as a can of ether, and you can graft without even the consent of the patient, or, in fact, the patient hardly knowing what you are doing.—*Bos. Med. and Sur. Jour.*

THE TREATMENT OF SUPPURATING BUBOES BY INJECTIONS OF IODOFORM OINTMENT.

The frequency of suppurating glands in the groin, says Dr. William K. Otis, resulting, as they may, from any one of the venereal diseases, from tuberculosis or trauma, renders this affection one with which we are frequently brought in contact and it is one which is especially obdurate to all recognized forms of treatment.

The so-called abortive treatment, either by pressure, the application of the actual cautery, the inunction of green soap, or any of the various methods which have been so frequently advocated, while ideal in conception, is so unreliable and, except in cases of very mild infection, so inefficient that when apparently it does succeed we are usually in doubt whether the gland would have gone on to suppuration without any treatment whatsoever.

The good, old-fashioned method of freely laying open the abscess and allowing it to drain and granulate for weeks, renders the patient exceedingly uncomfortable during that period, permits of the infection of other glands of the same chain and leaves a well-marked and telltale scar.

Excision of all implicated glands, the ideal method from a surgical standpoint, means a difficult and to some extent, a hazardous operation in a dangerous anatomical neighborhood, the retention of the patient for some weeks in bed and a scar, compared with which that resulting from the old method is but trifling.

On these accounts I was led, as far back as 1886, to try a method advocated at that time by Dr. Scott Helm, who withdrew the pus from the abscess cavity in suppurating buboes by means of an aspirator, washed it out with a solution of carbolic acid and refilled it with a mixture of iodol and vaseline, and who reported in August of that year, a series of twenty-three cases, only one of which remained uncured by this method.

At that time, however, while very well satisfied with two cases so treated, I was unable to pursue this method, and it was not until 1880, when Potain reported a series of forty-one cases treated by the injection of a mixture of iodoform and vaseline, one-half of which recovered in less than five days and the longest in twenty-three days, that I was again induced to try this plan of treatment.

The skin, for some eight or ten inches about the affected area was rendered thoroughly aseptic by scrubbing with green soap, washed with sulphuric ether and then douched with a solution of mercuric chloride 1-1,000. A narrow bistoury was then inserted into the abscess cavity and the contents gently but thoroughly squeezed out. The cavity was irrigated with a solution of mercuric chloride 1-1,000, and immediately filled to moderate distension with warm iodoform ointment (10 per cent.), care being taken not to use a sufficient degree of heat to liberate free iodine. The syringe used for introducing the ointment was the ordinary cone-pointed, glass, clap syringe. The plunger being removed, the barrel gently warmed in the flame of an alcohol lamp, was filled with ointment by means of a spatula and the plunger replaced. On finishing the injection, at the instant of withdrawing the syringe from the wound, a compress wet with cold bichloride solution was applied, which instantly solidified the ointment at the orifice, preventing the escape of the contents of the abscess cavity. A large compress of dry bichloride gauze was then applied, covered by a protective dressing of cotton and retained by means of a firm spica. The patient was requested to return at the end

of four days. If all was well at this time the dressing was simply re-applied, but if there were any evidences of inflammatory action, the wound was thoroughly irrigated and cleansed and the injection repeated.

Of sixteen cases so treated, nine were cured in six days, three in twelve days, one in fourteen days, one in twenty-three days, and two deserted during treatment.

The advantages claimed for this procedure are:

1st. That it is simple and safe.

2nd. In suitable cases cure, as a rule, seems to be more rapid than by any other method.

3rd. That the patient is not prevented from going about during treatment.

4th. The first gland being rendered thoroughly aseptic, renders it less likely that other glands in the chain will become infected (?)

5th. *It leaves no tell-tale scar.*

6th. It in no way interferes with the performance of any subsequent surgical procedure, if such should be deemed advisable.—*Jour. Cutan. and Gen.-Urin. Dis.*

MICROBE KILLER DEFEATED.

Dr. Robert G. Eccles, of Brooklyn, N. Y., has gained his suit against Wm. Radam, the Microbe Killer, for libel. The jury has decided that Wm. Radam shall pay to the doctor the sum of $6,000, and in addition shall pay the costs in the suit, all for the privilege of calling the doctor a charlatan and a quack. The verdict is one to be commended by everyone who is interested in the moral and professional standing of not only the physician, but also the pharmacist, as against the quack nostrum manufacturers and venders.

The people, represented by a court and jury, have decided that the nostrum makers cannot with impunity defame the good name and professional standing of men who do not cater to their questionable methods of providing remedies (cure-alls) for the ills of mankind. Radam, it seems, has gone a peg farther, and includes the diseases of the brute creation in the category of what his remedy will cure.

It will be remembered that Dr. Eccles in 1889 analyzed and published a formula for Radam's Microbe Killer, together with a lengthy article in the *Drug. Circ.* In this article the doctor very properly pointed out and held up to ridicule the enormous and inconsistent claims for this worthless cure-all. The analysis and comments upon the same must have touched closely upon facts, or else the Microbe company would not have retaliated in the unbecoming manner in which they did. They ignored the right of a chemist to analyze any substance which he pleases, and apparently held to the fallacious theory that secret nostrums are entitled to a special exemption from investigations of the analytical chemist, and that an analyst has no right to publish the result of his labors.

A few extracts from Dr. Eccles' original article on this question might very properly be quoted at this time, and which would serve well to give the gist for the emanation of the attack on the character of the doctor and his subsequent suit for damages:

"A Texas gentleman by the name of Radam, tiring of the dull drudgery of raising young trees, cabbages, tomatoes and flowers for a living, is now posing, throughout the United States, as a great philanthropist because of a wonderful discovery he claims to have made that is about to revolutionize medical science. If the reader will mix the following together he will have a product identical with Radam's wonderful 'Microbe Killer' (No. 1, there being four strengths) at a cost of less than five cents per gallon:

℞

Oil of Vitriol (impure)	4 drachms
Muriatic Acid "	1 drachm
Red Wine, about	1 ounce
Well or spring water	1 gallon.

"Mr. Radam and his agents only charge three dollars per gallon therefor, but then they throw in the jug as a part of the bargain. This nurseryman, who glories in knowing little or nothing of either medicine or medical science, evidently knows how to count cent per cent. on the first cost of his stock.

"In sheer derision of the unwarranted

broad claims of 'patent medicines' it has been customary to call them 'cure-alls.' To what manner of hyperbole shall we now resort when the proprietor of this new compound guarantees it to be a *never-failing cure for everything?* (Italics ours.) It is positively asserted that 'there is no disease in the *world* that will not yield to the microbe killer." Mr. Radam starts out with the intention of out-quacking the worst of quacks of this or any other age. If boldness of claim and dense, dark, crass ignorance of the subject, he pretends to know best, count for anything, then surely, he takes the lead of all who have preceded him on the same route.

"The company bearing his name, and presumably by his consent, send out descriptive pamphlets that are marvels of inaccuracy, and manifestations of phenomenal ignorance in bacteriology. Sulphuric acid the principal constituent of the 'microbe killer' outside of water, is a slow but cumulative poison. The kidneys are unable to excrete it, and after absorption from the stomach into the blood it has to return back into the alimentary track lower down and pass off with the fæces. Stillè in his 'Therapeutics and Materia Medica' says of it:

"'By habitual use this acid becomes very injurious to the teeth, even when greatly diluted, it whitens them, indeed, but also corrodes them. It also, sooner or later, enfeebles the digestion, produces colicky pains and diarrhœa, and impairs nutrition. Marasmus and even death may be the ultimate result of its use.'

"This is the stuff ignorant people are being beguiled into paying 6,000 per cent. profit to secure a diluted supply of. Where are our boards of health, and what are they doing that these men are allowed to urge everybody who suffers, however little, from any malady to take it indefinitely? Their claims are false, as all who are posted upon the subject know. It is downright humbuggery to speak of all diseases being caused by microbes. What can be the object of this Microbe Killer company in telling the public that physicians give their remedies solely to kill microbes? Surely they must know that this is as far from the truth as mortal man could possibly get. When this company tells us that fungi are animals they cap the climax in the ridiculousness of their position."

At this point the doctor discusses from the modern scientific standpoint the action of acids and alkalies and other antiseptics upon microbes, and shows conclusively the accepted scientific theory of the varied effects upon different germs, and furthermore shows that all diseases do not originate from one and a certain microbe, hence are not susceptible to, and cannot be controlled or cured by one universal remedy. He further states "that Radam's claim is simply laughable to all who know the nature of microbes. If the man (Radam) had ever known anything about the subject, so lamentable an abberration of mind would be clear proof of insanity."

While the article treats somewhat exhaustively upon the subject, it should not be regarded as tedious, for the points brought forth against the extravagant claims of quacks not only hold good in the case of the Microbe Killer, but also in regard to all other quack nostrums for which such broad, incongruous claims are made.

There can be no doubt that no more objectionable or pernicious class of goods are to be met with on the market than a large majority, if in fact, not all of the worthless nostrums which buoy up by false representations the failing strength, for a time, of the really afflicted, thus leaving the patient, when the false hopes have collapsed, in a condition from which recovery by proper medical treatment is far more difficult, and in many cases next to impossible. Not only this, but many times the fears and anticipations of disease in the minds of the hale, though weak-minded, are excited by the platitudes of the quacks, and in so far as this influence extends just so far are they robbing the poor and innocent of hard-earned money. —*New Idea.*

One Ray of Comfort.

"Hello, Rivers! You seem to have a bad cold."

"Worst I ever had, Banks."

"I'm sorry for you, old fellow. Wish I knew of something that would cure you, but I don't."

(With tears in his eyes.) "Give me your hand, Banks! You're the only man I've seen for three days that hadn't a sure cure.—*Chi. Trib.*

CURRENT LITERATURE REVIEWED.

THE AMERICAN JOUNAL OF OBSTETRICS for May contains an article by Dr. Charles P. Noble on

Certain Problems in Abdominal Surgery, based on One Hundred Celiotomies.

The author declares the essentials of success in abdominal surgery are:

I. Early operation.

II. Careful preparation of the patient, with especial reference to stimulating the emunctories and to securing asepsis of the abdominal wall.

III. An aseptic operating room.

IV. Aseptic hands and instruments for the surgeon.

V. As great rapidity in operating as is compatible with careful, thorough work.

VI. Irrigation and drainage in septic cases.

VII. Careful after-treatment, embracing especially the withholding of fluids for about forty-eight hours, early purgation and at least three weeks confinement in bed.

The advantages to the patient of early operation are carefully considered in the paper and the dangers of delay pointed out. The question of drainage is also thoroughly gone into and the results of various operators without drainage noted. The author believes drainage to be of great service in septic operations and in those cases in which it is necessary to separate many vascular adhesions. As to the charge that glass drainage produces fecal fistula, the author thinks that the Scotch verdict of "not proven" must be returned. The paper includes tables showing the disease for which the operation was performed and the results of operation. The report also includes several cases of post-operative ventral hernia. The author regards as causes of post-operative ventral hernia:

I. Extreme malnutrition of the patient when operated upon.

II. Failure to approximate the divided transverse aponeurosis.

III. Suppuration of the abdominal wound.

IV. Drainage.

V. Early rising from bed.

VI. Too early return to work.

VII. Failure to wear a bandage (?).

Dr. Mary A. Dixon Jones concludes her scholarly paper on

Colpo-hysterectomy for Malignant Disease.

The later statistics of the operation are given, the literature of the subject having been consulted down to the present year. The author unhesitatingly decides in favor of complete removal of the uterus as against the amputation of the cancerous cervix, quoting from various operators to fortify her position. The limits of vaginal hysterectomy are also discussed and the technique of the operation minutely described. The author decides that the vagino-peritoneal opening should not be closed as the drainage in these cases is often great and the open method allows of its proper discharge. She has found that the best results are obtained by removing the dressings a few hours after operation and, after the first day, once in twenty four hours till the wound is healed. She has also found that the ealier and freer the evacuations of the bowels the better for the patient and, as after laparotomy, she has usually tried to have a free evacuation of the bowels on the second day. In regard to the question of the use of forceps or ligatures in securing the broad ligament the author states that she uses either as the circumstances of the case make most convenient.

Dr. George J. Englemann reports.

An Unique case of Extra-uterine Fetation.

The patient had been treated for pelvic trouble for which operation had been proposed and declined by the patient. The patient gradually recovered her health and some years later was seized with an attack of abdominal cramps, as she stated, for the purpose of deceiving her attendant, being unmarried and probably fearing pregnancy. She gradually became septic and died; the post mortem revealing a tubal pregnancy, an illustration of which is given in the paper. Dr. Englemann states that he saw the patient but casually during her last illness and urged the necessity of operation, in which opinion the attendant did not concur. Dr. Englemann also states that the symptoms pointed rather to appendicitis than an extra-uterine gestation.

Dr. Charles A. L. Reed reports a case of "The Second Occurrence of Ectopic Gestation in the Same Patient." The second operation was performed for intestinal obstruction, the ectopic gestation being accidently discovered during the operation. The patient recovered.

Dr. M. F. Cuthbert reports cases of "Acquired Venereal Disease in Children."

Dr. S. Marx discusses

Duehrssen's Methed of Deep Cervical Incisions in Cases Requiring Rapid Delivery.

The author gives the indication for the procedure as follows: "In the great majority of cases the operation is permissible shortly before or during labor, when the supra-vaginal portion has disappeared. Upon this point Duehrssen lays particular stress. Where the supra-vaginal portion is present he advises that blunt dilatation with the finger or instrument should precede his incisions, they being made only when the supra-vaginal portion has nearly or entirely disappeared. In multiparae where the supra-vaginal portion is abnormally rigid or consists of cicatricial tissue, as from an old cervical laceration, incision of the supra-vaginal portion may be called for. The operation, according to Duehrssen, is also indicated in the rigid os of old primiparae where the ordinary remedies fail; in cases of premature artificial rupture of the membranes; placenta previa; eclampsia, especially in primiparae; prolapsus funi in old primiparae; in cases of flat, rachitic and generally contracted pelves to afford the

accoucheur the oportunity to apply the forceps at the time when the position of the head is most favorable." To the author's mind the operation is called for, in an overwhelming majority of cases, by eclampsia. For these cases he does not know of one operation where speed and rapidity of action can be so relied upon as in the procedure recommended in the article. In both the cases reported by the author in his paper, the interval was less then fifteen minutes from the time the cervix was incised until the delivery of the placenta. "Another condition, not mentioned by Duehrssen, where the operation must be of signal assistance, is in accidental hemorrhage before or during labor. "In these cases little, if anything, can be done before the uterus is emptied." As to the method of operation — "Duehrssen advises the use of a pair of scissors of large size. It is necessary to thoroughly disinfect the vaginal tract and vulva. The lower uterine segment is seized through the speculum by a pair of stout bullet forceps, and the tissues cut, dividing the cervix from the vaginal junction down. This is done on four sides." In his own cases the author used a long sharp bistoury, believing that the incisions can be more carefully done and that the cut is cleaner than by the scissors. No speculum was used. "The uterus is steadied by a pair of bullet forceps. The index finger is carried into the cervical canal to a point corresponding to the cervico-vaginal junction. The knife, guarded by and between the index and middle fingers of the other hand, is passed along the vagina to the junction of the cervix and vagina. When the fingers of both hands meet, the point of the knife is pressed against the finger inside of the cervix and both are withdrawn at the same time, the point of the knife continually in contact with the finger to prevent its injuring the vagina. This manoeuvre is repeated until the incisions are made on four sides. In those cases in which the supra-vaginal portion is present the advice given is somewhat modified. Blunt manual or instrumental dilatation until this portion has nearly or entirely disappeared — i. e., merged into the uterus — should be followed by the deep incisions." In the two cases which the author reports in his paper, he did not meet with any serious hemorrhage and the only remaining trace of the operation after recovery was a slight stellate laceration of the cervix.

Dr. Reuben Peterson reports "A case of Rupture of an Ovarian Cyst." The site of rupture was clearly shown in the cyst wall at the time of operation, nearly a year subsequently.

Dr. Irving W. Smith contributes a short paper on the

Surgical Treatment of Cranial Infraction in a New-born Infant.

The mother was a dwarf and the labor required the use of forceps. The presentation was right occipito-anterior. The application was high, and the impingements of the tips of the blades of the Hodge instrument were on the left frontal eminence and over the right ear. During extraction a sense of something giving way was felt for a moment and on emergence of the head there was found a depression of the cranium on the right side of the frontal bone. The child was large and vigorous, but it hardly slept or nursed and was restless and crying constantly. On the fourth day it was decided to treat the case on general principles. The infant was anaesthetized, the scalp opened and the bone divided by Hey's saw transversely to the depression axis. The bone was lifted by the elevator applied successively on either side of the saw track. A slender, long spicule was removed. There was some free venous hemorrhage but no shock, and the child slept and nursed normally from the hour of the operation. Primary union followed and a month later the infant seemed perfectly well." The reporter believes the injury was caused by unskillful application of force, bringing the injured part across the promontory of a strongly curved sacrum.

Dr. J. N. Martin, reports a case of "Fatty Uterus — Removal — Recovery." After the operation, an examination of the uterus revealed the cavity surrounded on all sides by fat from two to three inches in thickness; this was surrounded by the serous membrane with a few fibres of muscular tissue, in all about one-sixty-fourth of an inch in thickness. The operation was performed for persistent menorrhagia.

THE VIRGINIA MEDICAL MONTHLY

For May contains an open letter from Dr. G. Frank Lydston to Dr. Hunter McGuire on the subject of

Sexual Crimes among the Southern Negroes Scientifically Considered.

In his letter Dr. Lydston reviews the whole negro question in a thorough and impartial manner, maintaining the middle between wholesale condemnation and sickly sentimentality. The demoralizing effect of sudden freedom, with the accompanying necessity for independent thought and action, in a race accustomed to being thought for and taken care of and but little removed from absolute savagery, receives proper attention as one of the factors. He also alludes to the want of morals which, sometimes existed between master and slave under the old regime, as perhaps accounting somewhat for the condition.

Dr. R. A. Lancaster discusses the subject of

Simple Continued Fever.

The name is objectionable in that it gives no idea of its etiology or pathology; but until its cause is better understood, and its pathology further investigated we must be content with a name which does not mislead if it gives no information. He believes that the *materies morbi* of this fever is an unclassified germ, entirely different from the germs of typhoid or of malarial fever. The only evidence he has to offer in support of this theory is taken from a clinical standpoint, but he believes the day is not far distant when the microscopist and the bacteriologist will sustain this view. It has been

his observation that this fever is more prevalent in spring and early summer, before the advent of our rainy season, and that it occurs more frequently where the surroundings are unsanitary than where thorough sanitation prevails. The evidence would go to prove that, like typhoid fever, the cause of simple continued fever is of animal origin; but, while its habitat may be the same as the typhoid bacillus, its manifestations are as unlike and distinctive as are those of variola and varicella, as measles and scarlet fever. It has *per se* but one constant and essential symptom and that is pyrexia. All the other manifestations are the result of pyrexia, and are as varying as are the effects of pyrexia on different individuals. There seems to be good grounds for the popular belief that this fever, as well as other forms of continued fever, is likely to leave on some multiple of the seventh day. Oftentimes there will be an abrupt termination on the fourteenth or twenty-first day with no subsequent rise. At other times the first complete remission will occur on these days—the temperature being normal or subnormal for one, two or more hours, with a rapidly shortening period of pyrexia each day. For treatment he uses calomel in two grain doses combined with soda, every two hours. As a means of diagnosis and to eliminate any malarial element he gives quinine in fifteen to twenty grain doses *per diem* for the first three days. The antipyretics he has also found of service. Cool sponging or a cold douche to the head are of advantage.

Dr. George M. Kober contributes a paper on "The Etiology, Distribution and Prevention of Land and Ship Cholera," reviewing the characteristics of the bacillus, the causation and symptoms of the disease and the precautionary measures that should be taken to prevent its importation or to suppress an outbreak.

Dr. Johnson Eliot reports a case of Mastoid Abscess and discusses the subject of

Mastoid Disease.

In all severe cases of inflammation of the middle ear there is more or less involvement of the mastoid. We may have inflammation of its periosteum or caries with formation of abscess in some part of the cavity, the first often arising from acute catarrh. Caries and necrosis when found in the mastoid, are due to imperfect removal of pus. Sclerosis and hyperostosis sometimes result from mastoiditis. Pain, tenderness, redness and swelling in the mastoid region, direct us in making a diagnosis. Neglected cases may discharge externally and relief be obtained. Pus may be carried through the mastoid vein and enter the lateral sinus, causing pyæmia. Paralysis of the seventh nerve may occur on account of its passing through the Fallopian canal. Erysipelas and abscess of the neck, and also brain symptoms, may develop. Cases of congestion and periostitis of mild type usually yield to a few leeches followed by poultices. If these are not effectual, a Wilde incision should be made. Slight hemorrhage occurs from the posterior auricular artery. The depletion will be beneficial even though pus be not present. It is best not to delay the operation after the diagnosis has been made in the hope that necrosis will cast off the bone. Anodynes and leeches do not relieve the pain, which is relieved by firm pressure. Often, where there is a purulent discharge into the external meatus, we find granulations. In the more severe cases, after making an incision to the bone, immediately back of the auricle, an opening to the bone should be made; or, if an opening exist already it should be enlarged. An ordinary dressing should be used and the wound allowed to granulate from the bottom. Sulphide of calcium seems to exert an influence over suppurative diseases of the ear as well as elsewhere.

Dr. DeWitt Webb contributes a paper on "The Influence of Immaturity and Degeneration in Some Forms of Thinking—Especially Sexual Thinking."

Dr. Stuart McGuire discusses "Drainage after Abdominal Section," reporting a case where the tumor removed weighed seventy-seven pounds. The patient made an uninterrupted recovery. His conclusions are: In simple cases, use drainage by purgation. When complications indicate direct drainage, use the glass tube. When combined hemotasis and drainage are required, or adhesions desired, use the gauze. In some cases a combination of the different methods is advisable.

Dr. Edwin L. Morgan contributes an interesting paper on "Syphilis — Its Age and Relation to the Antiquity of Man." The literature on the subject is carefully and thoroughly considered in regard to the existence of prehistoric syphilis both in America and in Europe. The author is not a believer in the American origin of the disease and believes that it is as old as our race. "As to its origin or whence it came, the *silent* page of history can only tell."

Dr. Benjamin H. Brodnax describes an "abdominal corset" used by him in cases of "Chronic Fermentative Diarrhœa in Children, due to torpidity and relaxation of the bowels." He combines the use of the appliance, (which is made of a strip of cotton flannel long enough to reach from the pubes to the breast bone and wide enough to reach nearly around the abdomen, and fastened at the back by means of tapes) with the small doses of salol. His idea is that the intestines are distended by fermentative gases and cannot force out their contents or absorb the nutrient juices necessary to life. By compressing the abdomen, the intestines regain their normal contractility, and by emptying themselves, cure is set up; "and the peevish, fretful infant, relieved of the constant neuralgia of the bowels, becomes happy and healthy."

Dr. B. F. Travis discusses the subject of "Acute Purulent Inflammation of the Middle Ear." Other papers are: "Imperfect Articulation, Stammering etc.,—Their Cause and Cure" by Dr. Frederick Sohon; "Multiple Retro-pharyngeal Abscess" by Dr. John Dunn; and the report of a "Case of Supra-pubic Cystotomy" by Dr. Charles Minor Blackford, Jr.

PERISCOPE.

MEDICINE

Faults in Voice Production which Lead to Voice Disease.

Lennox Brown (*Jour. Lar., Rhin, and Otol*). Defects in methods of speaking and singing are much more potent factors in production of voice failure than diseases of throat and nose. There are three elements concerned in the formation of the voice, which may be seat of the defect.

First. The *motor*, that is the lungs representing respiration.

The lungs should be inflated by means of the diaphragm and intercostal muscles, avoiding collar-bone breathing.

The breath should be economized in allowing it to escape from the lungs, and breath should not be taken too frequently.

The "attack" upon a tone should be calculated with just enough force to permit the proper adjustment of the vocal bands for that particular tone, faulty attack causes a lack of co-ordination.

Second. The *vibrating* element, situated in the larynx.

The most common defect here is carrying the registers too high before changing to the one above, and tremolo and vibrato.

Also raising the pitch of the voice instead of raising the voice itself.

Third. The resounding element, dependent upon properly shaping the resonating cavity, that is the chest walls, windpipe and all the pharyngeal and nasal cavities.

Also want of contracting power of soft palate. Voice gymnastics can accomplish much in overcoming these defects.

For Chronic Bronchitis and Emphysema.

GYNECOLOGY.

Varicocele In Women.

The foreign correspondent of the St. Joseph *Medical Herald* says: To change the subject, what do you think of the lately enunciated opinion that varicocele is quite as frequent in women as it is in men, but that we do dot know its symptoms? A late work on the subject by M. Roussau, who had seen the cases in Dr. Pozzi's wards, explains this malady which is called "pelvic varicocele." It has been noticed in making laparotomy and hysterectomy, and in autopsies made on women, that varicose dilatations of the pelvis are very common, just as hemorrhoids and varicose veins of the leg are in women. Pelvic varicocele comes from any cause that brings about any interference with the venous circulation of the pelvis, such as tumors, cysts of the ovary, as well as the large class of fibroids, etc. There is also a general state that predisposes to this malady; a sort of atony of the smooth fibers of the muscular structure of the veins, which is very often under the influence of certain diseases. The symptoms of varicocele in women are analogous to those in man; pain in the left side of the pelvis, running downwards into the groin and back upwards to the lumbar region, with feeling of weight in the part, most felt at the monthly period. It goes away when the patient is lying down, and comes back when she walks. In making an exploration, varicose veins may be seen on the labia majora and the finger will find a tumor that is soft and painful to pressure. This will be more prominent when the patient is standing. By the rectal touch it can be felt very well, and may be taken for salpingitis. The symptoms are not very evident in many cases but the malady should be sought for however, in all varicose cases. The treatment must address itself to the cause, but in case of pain, rectal injections of laudanum solution are ordered, while the patient is kept in bed. To diminish the congestion and help the circulation along, hot water rectal injections are used, with a rectal sound that will carry the water some eight or ten inches up; a small porcelain ring is held in the anus to allow the water to flow away, and as much as five or six quarts are used. A vaginal tampon is also advised, to make compression on the vessels. Hydrastis canadensis and hamamelis are given internally.

NEWS AND MISCELLANY.

Haydn's Sacred Oratorio, "The Creation," will be sung for the benefit of the Methodist Episcopal Hospital, by a chorus of 300 voices, under the direction of Caspar Fischer, Jr., at the Academy of Music, Thursday Evening, May 25, 1893. Germania orchestra. Soloists: Madame Seulke, Soprano; Leonard E. Auty, Tenor; Emil Fischer, of New York, Basso. A. Rittenhouse, D. D., Supt. of Hospital.

ARMY AND NAVY.

U. S. ARMY FROM MAY 7, 1893, TO MAY 13, 1893.

Captain Louis Breceemin, Assistant Surgeon, U. S. Army, is relieved from duty at Presidio of San Francisco, Cal. and ordered to Columbus Barracks, Ohio, for duty.

1st Lieut. Charles Willcox, Assistant Surgeon, relieved from temporary duty at Angel Island, Cal. and ordered to Presidio of San Francisco, Cal. for duty.

Leave of absence for 20 days, to commence about May 24, 1893, is hereby granted, Major Curtis E. Munn, Surgeon, U. S. Army.

Leave of absence for one month to take effect June 1, 1893, is granted Captain Walter D. McCaw, Assistant Surgeon, U. S. Army.

By direction of the Secretary of War, leave of absence for six months on account of sickness, is granted Captain Robert B. Bevham, Assistant Surgeon, U. S. Army.

Captain Richard W. Johnson, Assistant Surgeon, relieved from duty at Fort Bowie, Arizona, and ordered to duty at Washington Barracks, D. C.

Captain William J. Walkemac, Assistant Surgeon, relieved from duty at Fort Bidwell, California, and ordered, to Fort Thomas, Kentucky, for duty.

A board of officers to consist of

Colonel Charles T. Alexander, Assistant Surgeon General

Lieut. Col. George M. Sternberg, Deputy Surgeon General

Major John Van R. Hoff, Surgeon, is appoited to meet, at the call of the president there of, at New York City, for the examination of such officers as may be ordered before it, with a view to determining their fitness for promotion.

Captain Curtis E. Price, Assistant Surgeon, ordered to report in person to the president of the examining board at New York City, for examination for promotion

Captain Blair D. Taylor, Assistant Surgeon, will report in person to Lieut. Col. Dallas Bache, Deputy Surg. General president of the examining board, convened at Omaha, Neb. at such time as he may be required by the board for examination as to his fitness for promotion.

U. S. MARINE HOSPITAL SERVICE FOR THE FOUR WEEKS ENDING MAY 6TH, 1893.

Bailhache, P. H., Surgeon, to report to Superintendent of Immigration for temporary duty, April 24th, 1893.

Purviance, George, Surgeon, detailed as Chairman Board of Examiners, May 6th, 1893.

Gassoway, J. M. Surgeon, granted leave of absence for two days, April 19th, 1893, detailed as member of Board of Examiners, May 6th, 1893.

Stoner, G. W., Surgeon, detailed to represent Service at International Congress of Charities, etc., Chicago, Illinois, May 3rd, 1893.

Irwin, Fairfax, Surgeon, to proceed to Naples, Italy, for temporary duty, April 17th, 1893.

Carter, H. R., Surgeon, detailed as Recorder Board of Examiners, May 6th, 1893.

Wheeler, W. A., to proceed to Europe as Inspector, April 17th, 1893.

Banks, C. E., passed Assistant Surgeon, to proceed to Grasse Isle Quarantine Station, Canada, for duty.

Carrington, P. M., passed Assistant Surgeon, to proceed to Hamburg, Germany, for duty, April 17th, 1893; to proceed to Marseilles, France, for temporary duty, April 28th, 1893.

Geddings, H. D., passed Assistant Surgeon, to inspect Fisherman's Island, Virginia, May 6th, 1893.

Stimpson, W. G., Assistant Surgeon, to proceed to Quebec, Canada, for duty, April 29th, 1893.

Stewart, W. J. S., Assistant Surgeon, to report at Washington, D. C., April 22nd, 1893.

Branham, J. W., Assistant Surgeon, to proceed to New York, N. Y., for duty, April 21st, 1893.

Sprague, E. K., Assistant Surgeon, to proceed to Charleston, S. C., for duty, April 21st, 1893.

Prochazka, Emil, Assistant Surgeon, to proceed to Ellis Island, N. Y., for duty, April 18th, 1893.

APPOINTMENTS.

John W. Branheim, Virginia, commissioned as Assistant Surgeon, April 19th, 1893.

Ezra K. Sprague, of New York, commissioned as Assistant Surgeon, April 19th, 1893.

Emil Prochazka, of Wisconsin, commissioned as Assistant Surgeon, April 19th, 1893.

PROMOTIONS.

Assistant Surgeon J. C. Perry, commissioned as Passed Assistant Surgeon, April 19th, 1893.

Assistant Surgeon A. C. Smith, commissioned as Passed Assistant Surgeon, April 19th, 1893.

The World's Fair.

FINAL ARRANGEMENTS FOR THE SALE OF TICKETS VIA THE B. & O. R. R.

For the benefit of those desiring to attend the World's Fair the Baltimore & Ohio Railroad will sell Excursion tickets to Chicago and return, at all stations on its line, at low rates. Tickets will be on sale until November 1st, and will be valid for return journey until November 15th, 1893. They provide for a reduction of 20 per cent. below regular rates. These ticket will be valid only for continuous journey. Tickets at higher rates will be sold that will permit holders to stop over at Baltimore, Washington, or any other point, going and returning.

Besides the opportunity of visiting Washington, a privilege afforded by no other route, tourists via the Baltimore & Ohio Railroad will traverse the historic Potomac Valley, the theatre of the war between the States. At Cumberland they will be offered a choice of routes, via Pittsburgh, or across the Allegheny mountains, 3,000 feet above the level of the sea and via Deer Park and Oakland, the famous summer resorts. The scenery along the Baltimore & Ohio route is the most picturesque in America. Pullman accommodations may be reserved in advance of journey. For rates and information apply to nearest B. &. O. Ticket Agent, or Chas. O. Scull, General Passenger Agent, Baltimore, Md.

" **C. B. Brigham, R. B. Cole, Levi C. Lane, J. Rosenstirn,**	*SAN FRANCISCO*

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M. D, *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

NO OPENERS REQUIRED. FOR USE IN SICK ROOMS and families. By a recent and most practical invention no openers in future will be required for G. H. Mumm & Co.'s Champagne. To break the wire, bring the small seal to a horizontal position and bend from side to side till one of the wires is broken, pulling upward removes top of cap and wire—done in an instant.

CHAMPAGNE IMPORTATIONS. Custom House statistics of 1892 show G. H. Mumm's Extra Dry to be 75,880 cases, being more than one-fifth of the entire champagne importations and over 9,000 cases more than of any other brand. It is noted for its excellence, purity and natural dryness.

ORIGINAL ARTICLES.

OOPHORECTOMY IN DISEASES OF THE NERVOUS SYSTEM.

MARY A. DIXON-JONES, M. D., Brooklyn, N. Y.

I have read with much interest Dr. Allen McLane Hamilton's article on "The Abuse of Oöphorectomy in Diseases of the Nervous System." He says:[1] "In speaking, as I am about to, it is with a full appreciation of its value, which I believe is exceedingly limited, except where well-marked and previously recognized structural disease of the organs is determined."

I cordially agree with Dr. Hamilton that, in every case, the disease should be "well marked," and, I would still further emphasize the idea by adding that it should also be, as far as we can judge, *incurable, and manifestly doing positive injury to the system.*"

Previously recognized structural disease of the organs may be determined," and yet this not be sufficient to demand or warrant the removal of the ovaries; for structural changes may be considerable, and yet produced only by a slight inflammation and would not, therefore, justify extirpation. Even more profound changes of structure, resulting from more serious conditions will not, in all cases, render it necessary.

Dr. Hamilton says further of this operation: "Its value is exceedingly limited." I believe it is absolutely "limited," and should never take place for purely nervous conditions, but for absolute and incurable disease of the named organs, and maintain that, in no instance, for any nervous disease, should healthy ovaries be removed.

In 1882, Sir Spencer Wells said:[2] "Its introduction in mental and neurotic cases is only to be thought of after long trials of other tentative measures, and the deliberate sanction of experienced practitioners." In an article of mine published in the *Am. Jour. of Obstet.*, Feb., 1888, referring to the above, and quoting the following expressions from Sir Spencer Wells: "Removal of ovaries while in a state of functional activity," "Oöphorectomy, or removal of normal ovaries," I said: "I shudder at the thought of re-removing *healthy* ovaries, or even when the disease is problematical; I would not remove healthy or normal ovaries for dysmenorrhœa or any suffering in the regions of the ovaries; I would not remove them for epilepsy, nor for mental or neurotic disease, even if I had failed after long trials of tentative measures, and had the cordial, full and deliberate sanction of experienced practitions, *unless* I believed the *appendages* themselves *were diseased.*"

In an article, in the *N. Y. Med. Jour.*, May 10-17, 1890, again referring to the above, and quoting the following from Dr. T. A. Emmet:[3] "From the beginning, I have been uncompromising in my opposition to the removal of the ovaries for dysmenorrhœa and other nervous disorders, due to perverted or impaired nu-

1 N. Y *Med. Jour.*, Feb., 1893

2 *Am. Jour. Med. Science*, 1886, Vol. II., p. 463.

3 *Med. Record*, Dec. 28, 1889, p. 711

trition, and where the fault lies in the centres," I then add: "Thus it will be seen that the position which I assumed from the first, and published nearly two years before, is more conservative than Dr. Emmet's position. I make the 'uncompromising' sweep of excluding all cases from this operation, except where there is hopeless disease of the organs themselves; that is, I denounce the removal of the uterine appendages for any cause, neurotic condition, constitutional disturbance, or for any reason except for incurable disease. When thus diseased they are a continual injury to the system, and their removal is a lasting benefit. To remove healthy organs for any 'grave' condition of the general system should not be thought of, and cannot, under any circumstances, eventuate in any good; for the normal action and physiological function of healthy organs will always increase the life force, and assist in restoring the system, in whatever way diseased, to a state of health."

I have never conceived of any circumstances that would demand the removal of normal ovaries. I regard it as a most serious procedure to remove human ovaries, and it should not be done without sufficient reason any more than amputating a hand, arm, or leg. A woman is to be inconceivably pitied, who, from any cause, has to lose the organs, and yet, to many, it has been a blessing; it has been their salvation and the means of adding years to their lives. A man is to be inconceivably pitied who has tuberculous lungs or fatal nephritis, and would consider himself inconceivably happy if he thought it possible for him to live after the removal of the fatally diseased lungs or kidney, and especially if thereby his life could, for many years, be prolonged.

Another reason why the removal of the ovaries should, as much as possible, be avoided, and women urged to seek early to be cured of any ovarian trouble, is that continuous disease of the organs, not only interferes with health, but may render the person absolutely sterile. In my article on "Sterility in Woman,"[4] I gave a number of instances where special treatment had removed an incipient ovarian and tubal disease and with the best results. This, I believe, is really what was done in most of the cases, mentioned in the article as being treated for sterility; but I would especially refer to the two in the 5th paragraph, page 319. Perhaps few have had larger opportunities than I to read the innate longings of every true woman for children. I have heard the moan from the depths of the human heart. For more than twenty years my practice in the disease of woman has been largely to remove the causes of sterilty and, as I said in the above mentioned paper, "Planted deep in every true woman's heart is the love for children, and nothing is more beautiful than a large family of children; no greater happiness can come to a woman."

Dr. Hamilton further remarks in his article: "So far as as I know, oöphorectomy has never cured a case of well-established or even incipient organic disease, or has proved to be the least use except in functional disturbances that could have been cured, or at least helped by angencies of a far less dangerous nature." In this assertion I believe Dr. Hamilton would find many eminent surgeons and gynecologists who disagree with him. Battey says: "My cases of epilepsy have given me the most satisfactory results. The cures have been prompt and complete." He reports, in 1886, 13 cases of epilepsy cured by the operation. On another occasion he said nine out of ten of his cases of ovaro-epilepsy have been completely cured of their epileptic form of seizures.

Prof. A. Vanderveer[5], of Albany, gives several cases. One, 24 years old, had eleptiform seizures at 14. He operated for the removal of the uterine appendages, May, 27, 1886, and "four years after the operation she had yet no return of the convulsions." Prof. W. T. Howard says of a patient: "She would lie in a state of coma, writhing in pain for ten days together; she had taken her weight in bromides and chloral until they had no effect whatever." He removed the ovaries and tubes and said: "She recovered and was like a new being." Olshausen reports a severe case of hystero-epilepsy—"the troubles," he says, "were removed after castration."

Dr. Earnest Böhni[6], reports a patient,

4 Sterility in Woman—Causes, Treatment and Illustrative Cases. *Med. Rec.*, N. Y., Sept. 19, 1891.

5 *Tr. Med. Society*, N. Y., 1882, p. 182.

6 *Cor. B. Bl.*, Schweizer Artz Bas., 1886. XVI., p. 622.

25 years old. The epileptic fits were so severe that it required three persons to hold her, convulsions sometimes lasting three hours, and occurring many times a day. The left ovary was enlarged, inflamed and sensitive to the slightest touch. Dr. Böhni removed this and asserts that, from the day of operation, the patient had no spells. Dr. Reamy[7] reported a case of a young woman who had suffered from constant headache and epileptic attacks. She had been treated by various physicians without obtaining any relief. After the removal of the ovaries the headache ceased, the epileptic attacks did not re-appear, and the anxious vacant stare of the contenance entirely disappeared. Dr. A. Maurer, in Coblentz, reports the case of a young girl, whose menstruation appeared at seventeen, was irregular, accompanied by increasing pain in the abdomen, back and lower extremities; the general health became affected, the ovaries were sensitive to the touch. After a while the severe periodical pains became epileptic in character, patient at times unconscious, extremities rigid, body opisthotomous. To make the diagnosis more certain he had the patient chloroformed; the ovaries were found to be enlarged, and if either one was taken between the fingers, notwithstanding the deep narcosis, there were tetanic convulsions of the whole body. He concluded: "The cause of the sickness was the disease of the ovaries. He removed both organs, and reports a complete recovery of the patient."

I find a case reported by Jacob May, M. D.[8] "The patient, 31 years old, taken in her third pregnancy with epileptic seisures; they continued increasing in severity, and became so violent as to require the united strength of several persons to prevent her from injurying herself. The doctor recognized that there was tenderness in the region of tubes and ovaries, and consulted with Prof. T. G. Gaillard Thomas, of New York, who, after a thorough examination of the case wrote: 'In my opinion, Mrs. A. suffers from hystero-epilepsy, due to ovarian and tubal disease. You have done all for her which medicine can effect, I unhesitatingly recommend Tait's operation. The tubes and ovaries were removed. Sixteen months after the operation the patient wrote: 'I have had no fits and no symptoms of any. I am improving every day, and more able to do for my family than for years past.'" On May 21, 1888, Dr. May wrote: "Nearly four years have passed since this operation, and there is no return of epileptic seisures."

Dr. H. M. Boldt,[9] gives some most instructive cases. One patient, age 24, both ovaries were prolapsed and very sensitive; pressure on either brought on a feeling as though the patient would have a convulsion. Years of medicinal treatment and continuous local treatment had been of no service. The ovaries were removed. Gradually the convulsions diminished in severity and frequency, and now more than a year has elapsed since the last attack. Another case: Patient æt. 28 years; right tube and ovary much enlarged, prolapsed, bound down by perimetric adhesions and very sensitive, pressure on the ovary brought on hysterical convulsions. On February 12th, 1886, the right appendage was removed. After the operation the nervous symptoms disappeared, and since the patient has not had a convulsion.

Dr. Chas. Meigs,[10] reported a case of Hystero-epilepsy. "Patient had always enjoyed good health till after the birth of her child, six years previously. She was in bed nine weeks after her confinement; and six months after, she commenced having epileptiform seisures at her menstrual periods. They gradually became so violent that the family were about to place her in an insane asylum, when, Oct. 3, 1881, the ovaries and tubes were removed. The patient made a speedy recovery, and has not had one seisure since the day of operation. Donnell Hughes,[11] reports three cases, all had disease of the uterine appendages, these were removed; each patient recovered, and each one was afterward free from epileptic convulsions. Dr. J. G. Brooks reports a successful case of "Castration for Hystero-epilepsy." Dr. W. J. Asdale,[12] and Dr. Taber John-

son,[13] report similar cases with like results. Dr. T. Nelson, Prof. of Clinical Gynecology, Rush Medical College, Chicago.[14] "Patient 25 years of age, married six years, no children. The epileptic fits were becoming more frequent, and were worse just before the menstrual period. The ovaries were tender, adherent and displaced." The operation was done on Nov. 20, 1886, with satisfactory results; and he said to his class: "If such a case presents itself to you, and the patient has been under skillful treatment for five or six years, as in this case, without any material benefit, it will become your duty to operate."

G. H. Balleray,[15] Patterson, New Jersey, says: "A patient, aged 31, was brought to his office, Oct., 1881, to ascertain if anything could be done to cure her epilepsy. Convulsions began ten years previously, and had recurred regularly at each menstrual period, increasing in severity till the mental faculties had become impaired. The patient had been under the care of several physicians, all of whom administered the bromides in large doses. Both ovaries were found to be enlarged, and tender on pressure. I told the mother of the patient that her daughter could not be cured by drugs, but that the removal of the ovaries might result in a cure. In 1882, the convulsions had recurred with increasing violence at each menstrual period, and the patient was now suffering with acute mania, eyes red and glaring. She had been in convulsions all the previous night. The convulsions were followed by profound coma, out of this she passed into a manical condition. The patient, as well as the relatives, were very anxious for an operation. April 27, 1882, both ovaries and tubes were removed. Three months after the operation she had a slight convulsion. She then went fourteen weeks without having a convulsion, then she went four months without an attack; and when I last heard from her, five months had elapsed without a convulsive seisure." Prof. Lawson Tait,[16] reports a case of Hystero-epilepsy. The wife of a physician, 33 years old, Aug., 1887, married eighteen years; first child born ten months afterwards. In 1874, she aborted on the third month followed by pelvic peritonitis on the right side, and she was unable to leave her bed for three months. One year after she aborted again, and on this occasion a similar inflammatory attack occurred on the left side. In the spring of 1885, she was attacked for the first time with a convulsion which lasted about a hour, and similar attacks were repeated for two months, twice in twenty-four hours, which were very violent, sometimes requiring five or six persons to hold her. She made frequent attempts at suicide. The husband wrote, Aug. 5th: "She was seized worse than ever, the convulsions lasting from three to four hours, followed by wild delirium. This continued for eight days. Ten days since she became worse, and the mania that followed was of a suicidal character. I am certain that nothing will be of service except removal of the uterine appendages, as those in the right side have been diseased for eleven years." Prof. Porro was to remove the appendages on Aug. 17th; he commenced his operation at 11 o'clock, and finished by abandoning it at 12.15. He says both tubes and ovaries were so densely adherent, that it was impossible to separate them from the mass of organized tissue in which they were imbedded.

Aug. 30th, all the symptoms, including the violent convulsions, had returned with, if possible, greater severity. Four violent convulsions occurred in thirty hours, and she became insane. Mr. Lawson Tait performed the operation on the 23rd; removed the appendages from both sides; operation lasted nine minutes and a quarter. The patient has had no trouble since; is bright, cheerful, and the expression of her face entirely changed.[17]

The history of cases clearly shows, that many instances of epilepsy, of a remarkably serious character, have been caused by disease of one or more pelvic organs. Could anything be more natural, than that removing the cause, they would eventuate in cure? When we consider the large supply of nerves to the ovaries, and their multiplied connection with all

17 Dr. Chas. N. Dixon Jones, of New York, was, at that time, Mr. Lawson Tait's first assistant, and was present at this operation.

parts of the body, is it at all surprising that disease of these organs, especially in persons of a sensitive, impressible nervous system, should cause nervous disturbances, and possibly epilepsy? Is it any more improbable, than that epilepsy should be produced by slighter forms of irritation in other and distant parts of the body, as a tape worm in the alimentary canal, a tight prepuce; or, as J. Althamus[18] cites, a case in which "revaccination, in a healthy youth of 19, caused attacks of true epilepsy." Prof. Henry Hartshorn has said that, "losing a meal will, in the epileptic, cause convulsions." We have innumerable instances given where lack of development or inefficiency of the generative organs has caused acene. Dr. Edebohls showed me a case in his ward at St. Francis' Hospital, where repeatedly, month after month, at each menstruation, there was a marked and circumscribed skin eruption on the right side of the face and neck. We are also assured, by well authenticated instances, that reflex irritation from diseased ovaries has caused changes in the bone, or osteo-malacia, and equally well attested proofs of cures of this disease by removal of the effending organs.

Felding says: "Osteo-malacia is a reflex tropho-neurosis of the bones dependent upon ovarian activity;" and Thorn,[19] gives a case of a patient who had severe pains in the pelvic bones, with marked deformity, being unable to walk, and showing progressive emaciation and œdema. The diseased uterine annexæ were removed, after which the patient improved rapidly, the pains in the bones disappeared; she was soon able to walk, and a year after the operation, was perfectly well. Hoffmeier[20] reports the case of "a patient who suffered great pain in the bones, and increasing difficulty in walking, and finally was unable to do so without assistance." He performed "castration for osteo-malacia," after which the patient was well, had no further difficulty or pain in walking. F. Winckel, of Munich, and Prof. Schauta, of Prague, report similar cases with equally good results.

Ovulation is so important a function, that it is intended to take hold of the whole system, to embrace the whole being, for it is to perpetuate the race, and to give the best characteristics, mental and physical, of the individual. When this function is performed by diseased organs, will not the whole system, in a measure sympathize, and may not the nervous system and the mental conditions also to the same extent be affected? I have seen a number of cases where disease of the ovaries, not only produced local pains, but evidently caused the mental disturbances. Thomas[21] said: "Not a few women are always a little insane during the menstrual period." This can be said only of sick women, or those who have these organs diseased. Women with a healthy genital organization go through the function of menstruation as naturally, and normally, and painlessly, as the digestion of food, by a vigorous stomach.

In an article,[22] published Feb., 1888, I gave a cut, from my microscopical researches in diseased ovaries, representing "a varicose enlargement of a non-medullated nerve fibre packed in dense fibrous connective tissue," and, as I then said: "This is the first time, at least to my knowledge, that nerve fibres could be traced in inflamed ovarian tissue with such clearness as this specimen exhibits. Nerve fibres of this kind, so placed, will cause pains aggravated at every menstrual period; or, if in connection with the vaso-motor system, may cause epileptic fits." Such imprisonment and pressure of nerve fibres must frequently take place in ovaries where there are gyroma, these hard, dense, firm fibrous formations. I have,[23] in some instances, counted as many as five of them in one section of the ovary. I believe that when we have made more thorough pathological research, most of the cases of severe local pain accompanied by various neuroses, will be found in patients who have gyroma. I said in in another article,[24] "Out of a number of cases of epilepsy or hystero-epilepsy, I have, in three instances, performed oöphorectomy, not, however, for the epilepsy, but because I considered that the

24 Diagnosis and some of the Clinical Aspects of Gyroma and Endothelioma of the Ovary." *Buffalo Med. and Sur. Jour.*, Nov., 1892.

ovaries or uterine appendages were past cure, and their removal would benefit the patient, and it is remarkable that in each of these three cases of epilepsy, the ovaries were found to contain large gyromatous formations." When I visited La Saltpètrière, in Paris, I repeatedly walked through those immense old wards, with their hundreds of sick women, and had an opportunity of studying a number of those cases in connection with their history, and I now query, whether gyroma in the ovaries of these sick women would not account for many of their bodily sufferings, and the abnormal functions of the brain and nervous system. Esquimol and Moul have estimated "that derangement of menstruation form the source of one-sixth of the cases of insanity due to physical causes."

In Nov., 1882, I was called to see a patient, 27 years of age, subject to most terrific hystero-epileptic spasms. She was confined to her bed most of the time, nervous, sleepless, restless, pale, feeble and emaciated; had been twice married and no children. She had just passed through her supposed menstrual period, and had suffered all the night previous with agonizing pains, accompanied by almost continuous spasm and repeated convulsions. The uterus was found in extreme retroversion, and bound firmly down by inflammatory adhesions; on each side the uterine appendages were wrapped in an inflammatory mass, size of an ordinary orange, extremely tender and adherent to surrounding structures.

These conditions were, without doubt, the cause of the ill health of the patient, and of her serious nervous symptoms. Soon after her first marriage, at the age of 18, she had an attack of supposed "inflammation of the bowels," but which no doubt was gonorrheal salpingitis. Her health continued to grow worse, and soon after she commenced having epileptic seisures. These convulsions occurred first at the menstrual periods, and she often had as many as ten or fifteen during the night. She had been attended by many physicians, who in turn gave her bromides, electricity and Charcot's method of pressure, etc. I treated her continuously for months, in hopes of reducing somewhat the soreness and inflammation, but could see no essential improvement. What was to be done with these masses? Evidently the patient must die if she was not in some way relieved. Her multitude of doctors had all faithfully tried, and were powerless to help. These diseased masses could not be cured; they were of no service, and only a source of suffering—suffering so profound and incessant as to throw the whole body in violent convulsions and drive the poor woman to the verge of dispair and insanity. What else but to remove them? If Tait and Battey had not told us of this means of help, I should then have discovered it. Indeed without knowing what they had done, the necessity of such an operation was forced upon my mind. I even mentioned it to the patient. This was in Dec., 1882. Eagerly she seized the idea at once and repeatedly urged that it should be done, and even grew angry that I delayed. Said, "She wanted the operation if she died under it." So fearful were her convulsions that her excellent husband once said: "He would rather she would never come out of ether than be as she had been."

I still hesitated and delayed. In April, I requested Prof. B. F. Dawson, of New York, to see the patient. After a thorough examination he gave it as his opinion that the operation should be done, as soon as she could be made ready, that it was her only hope, and if not done, she could look forward only to a short while of miserable existence, and probably end her life in the insane asylum.

The 14th of May was fixed for the operation. The principal part was performed by Dr. Dawson. Dr. F. W. Rockwell administered the ether. Dr. J. H. H. Burge and Dr. C. N. D. Jones assisted. Every precaution was taken as to perfect antisepsis. On May 15, 1883, Dr. Dawson[25] presented the specimen to the N. Y. Obstetrical Society, mentioning that the "left Fallopian tube was distended to the size of an egg, and that he found the adhesion firmer than in any case on which he had operated, that it was with the greatest difficulty that he was able to remove the ovary, with its tube, and the right tube and ovary were borne down even more firmly than the left." These he did not succeed in removing. The patient succumbed to septicæmia on the 7th day. In my report

25 Amer. Jour. Obstet., Nov. 1883, p. 1192.

of this case to the Alumnae Association of the Woman's Medical College of Pennsylvania, subsequently published in the *Am. Jour. of Obst.*, I said,

"1st. This operation should have been performed on this patient five or more years before it was.

2nd. There was no other way to relieve her but by the operation

3rd. Without it she was in constant danger.

4th. The operation to her was not as much suffering, nor as much of a shock, or as great a trial as was a week of her usual suffering."[26]

A few weeks after the publication of the above-mentioned case in the *Journal of Ostetrics*, I received a letter from Mr. Lawson Tait, Birmingham, Eng., dated November 23, 1884, in which occurs the following sentence: "I agree with your conclusions concerning it absolutely. That poor girl's life would have been saved had the operation been done months or perhaps years before. The whole gist of modern abdominal surgery lies in an earnest aud continuous plea for early interference. There can be no doubt that the only regret about all such cases is that they are allowed to go on so long without operation."

Even if the epilepsy results from deep lesion of the nervous system, yet a disease of the uterine appendages will aggravate the conditions and be a source of increased suffering, and there is no reason why a person should not be relieved as much as possible. On May 30, 1888, a patient, M. G., was brought by her mother to see me at Throop Avenue Dispensary. She was an epileptic; the epilepsy following a severe attack of pelvic inflammation, the patient complained especially of the distress in the pelvis; said the suffered so much and so constantly that her life was no good. Examinations showed that she had had repeated attacks of peritonitis, one ovary was enlarged into a blood cyst, size of an orange; there was salpingitis of both tubes; and the appendages, on each side, were bound in by inflammatory adhesions. I informed the mother and daughter that these organs could not be cured; that, in the present state, they were not only a cause of increased suffering, but attended by some danger. The mother and daughter were both anxious that an operation should be performed. They called again and, in a few days, the mother brought the daughter to the hospital, 725 Green Ave. It was deemed advisable to perform the operation as soon as possible; it took place on Dec. 13, 1888.

The tumor was found to be a blood cyst, bound firmly by pseudo-membranous adhesions to the walls of the pelvis; so also were the other ovary and the tubes, and all gave evidence of long existing disease. The patient made an excellent recovery and was able to be up in two weeks, free from pain, and every day seemed to grow stronger and better, and did not at the time have a return of the epilepsy. The mother called frequently at the hospital to see her daughter, always expressed herself more than pleased.

As this operation seemed to be of such essential benefit I passed the patient over to the department of general surgery for the depressed bone of the skull to be raised, as so many physicians whom she had consulted, had considered this the cause of the epilepsy. This operation was successfully performed Jan. 25, 1889, and from it the patient made an excellent recovery, but, after it, the attacks of epilepsy seemed to recur, but they again gradually commenced to diminish in number. Certainly the patient was cured of her pelvic trouble, and to that extent her general system was benefited.

Both the last-named patients had chronic salpingitis, and the ovaries of each, from microscopical investigation, were found to contain large gyromatous formations. Those in the first patient were in a state of intense inflammation.

When the ovaries are thus diseased their removal does good, but when the organs are normal the operation can result in no benefit to the individual. I am so convinced of this that when I find a case, where the removal has been an apparent failure, I at once conclude that the organs were not diseased. Schrœder stated that he had operated 12 times for the removal of healthy ovaries for neurosis; three times with good results; one patient was well 8½, another 7, another 3 years after removal. He says emphatically of one, a case of severe hystero-epilepsy, "the

26 The day before the operation I saw her in agonizing pain, and when afterwards I saw the distended Fallopian tube and its thin walls, I marveled that it had not then burst and, probably, with fatal results.

young girl was entirely cured." In these three cases, that were apparently so benefitted, I venture to say that the ovaries were pathological though the report might say, "they were normal," or "very little changed." We cannot always tell by ocular appearance whether an ovary is diseased or not. Some of the most seriously diseased ovaries I have ever examined and which were removed because the woman had untold suffering—in some instances the sufferings were so severe that their lives were almost compromised—yet, from external or naked eye, appearances of the organs there were no special indication of disease. One such ovary I found, by microscopical examination, to be infiltrated with cancer; another had endothelioma so far advanced that it gave the patient the appearance of a far-advanced stage of phthisis. She suffered such distress that she could not work, and the organs were so sensitive that the marital relations were unendurable. Though at the time of the operation the ovaries did not show such manifest appearance of disease; still I *knew there was as much necessity for their removal as if they had been tubes full of pus.* I presented microscopical slides of a number of ovaries, so affected to the New York Pathological Society. I gave a specimen of one to Prof. Prudden, then president of the society, and sent a microscopical slide of the same ovary to Waldeyer, of Berlin. Both of these eminent pathologists, from a microscopical examination, returned a written diagnosis of "carcinoma," showing that in the estimation of these two distinguished authorities, it was a most serious form of degeneration.

In many instances the most experienced cannot tell by naked-eye appearances whether an ovary, even when freshly removed, is diseased or not; yet on one occasion I saw a few physicians, not experts, attempt to diagnose the condition of ovaries that had soaked for four years, part of the time in chromic acid solution, and part of the time in alcohol; and decide whether the surgeon was justified in removing them! "O tempore! O mores!" Many of these specimens were cases of pyosalpinx, some of endothelioma and chronic oöphoritis; one, where the right ovary and tube formed part of the wall of an abscess that extended into the adjoining pelvic aponeurosis; another where a pelvic abscess had most detroyed one of the Fallopian tubes; and another was the cirrhosed ovary of an old woman who had had removed an interligamentous tumor, 9 to 12 inches diameter. They might at least have recognized some disease from the remnants of adhesion.

Leaving this digression, I was insisting that it should be an established rule that ovaries should not be removed for abnormal mental conditions or any nervous disorder, unless there is a well recognized disease of the organs. It is not the abolition of the function that does good, nor because this function itself does harm, but it is, the ineffectual effort made to perform it by diseased organs. We have the report, that at the Samaritan Hospital, for Women and Children, Belfast, Ireland, [27] healthy ovaries and tubes were removed for masturbation and insanity, with no especially good results. This, of course, we might expect if the organs were normal. Dr. Wm. Lezynsky [28] reports a case of oophorectomy that took place at the City Lunatic Asylum, Feb. 23, 1880. "The patient had then been, for a period, extending beyond three months, in condition of catilepsy; receiving artificial alimentation, either by aid of stomach tube or enemata. On the 14th of February, at the suggestion of Dr. Allen McLane Hamilton, the inhalation of nitrous oxide was resorted to.

This patient had had no menstruation since her admission into the asylum, and the history of the case gave no indication of disease in the pelvis or of the pelvic organs; and there could be no reason for the removal of the ovaries, as according to the examination subsequently made by Prof. Wm. H. Welch, they were found normal. The patient died of septicæmia three days and twenty-two hours after the operation."

Prof. Allen McLane, in his article above quoted [29] further says: "I do not think this operation permissable in any case of insanity."

This is certainly true when said of healthy organs. No such operation should, under any circumstances, take place in case of insanity, unless the person has evident disease of the organs or tubes, and

29. *N. Y. Med. Jor.*, Feb., 1893.

this disease is doing positive damage to the system. Under those circumstances, I do not see why a woman should not be relieved as much as possible of suffering, whether she be insane or not. Eminent surgeons and gynecologists tell us that many insane women, who have been operated on in this way, have been cured of their insanity. "Of so called ovarian maniacs," Prof. Wm. Goodell, of Philadelphia, has reported "five cases, with four cures by removal of the ovaries." On this occasion, he said: "After the lapse of many years, my cases of oophorectomy for insanity, for hystero-epilepsy, for hysteromania showed positive and permanent benefit, adding: [30] "Should I meet with a case of insanity limited to the catemenial periods, I should not hesitate to remove the ovaries." He says further: [31] "What insane asylum does not hold incurable women, whose mental infirmities seem to depend upon the act of ovulation; or, at least, to be greatly exasperated by its recurrence. We have hitherto stood by with folded hands, dooming the sufferer to helpless invalidism, or to an untimely end. Fortunately, there is a remedy that promises much—one first proposed by Robert Beatty." Prof. T. G. Thomas says: "In one of his cases, the insanity was confined to the period of ovulation and, after the removal of the uterine appendages, the menstrual insanity was entirely relieved." Dr. Stansbury Sutton says of one of his cases: "After the removal of the diseased appendages, the patient's insanity soon disappeared, and she remained free from mental disease and nervousness." Dr. Noggerath [32] gives a case of "the disappearance of insanity immediately after the removal of an ovarian cyst." He emphasizes: "Immediately after the removal of the cyst, the patient had her reason restored."

Ed. Cotterell [33] tells of a patient, 37 years of age, who had long suffered from melancholia, and was always much worse during the catamenial periods. Immediately after the birth of her youngest and fifth child, she became quite insane, and more than once attempted to commit suicide. Menstruation very scanty, and attended with a good deal of pain. March, 1887, he removed the uterine appendages, and now nearly three years have passed, she has had no return of her old symptoms. According to his statement, both ovaries and tubes were affected. He says, "I know by experience that genuine menstrual epilepsy cannot be cured by drugs, and therefore I should have no hesitation in recommending the removal of the ovaries and tubes in any case in which medication has had a fair trial, without producing any beneficial result."

In July, 1887, I was called at the request of a physician in Bridgeport, Ct., to see a young woman in Ansonia, who had a long time been under treatment.[34] She was 27 years old, lying helpless in bed, a mental and physical wreck; married seven years, had no children, and was as incapable of being a wife as a mother. The uterus was found to be retroverted, dragged down by enlarged and diseased ovaries. She entered the Woman's Hospital of Brooklyn, July 12, 1887, brought to it in her husband's arms. She all the time had hallucinations, some of which could not be dispelled, often threatening to jump from the window, etc. The diseased ovary and enlarged tubes were extremely sensitive; and after some weeks' treatment, it was advised that they be removed. Dr. A. M. Jacobus was present and assisted at the operation. The patient gradually regained her mental and physical health, and when last heard from was well, and able to care for her household. A microscopical examination showed also that the patient had pyosalpinx, chronic oophoritis, and the ovaries contained gyromatous growths.

E. D. Bondurant,[35] M. M., admitted to the Ala. Insane Hospital, Aug. 23, 1871; 31 years of age, mother of four children, youngest child born Dec., 1870. Seven months after, she menstruated and immediately thereafter developed symptoms of mental derangement; the periods of comparative sanity were shorter. The evident close relations existing between the functions of ovulation and the mental symptoms led to the opinion, held by Dr. Bryce, and concurred in by Dr. J. Marion

Sims and Dr. Robert Beatty, to whom a statement of her case was submitted. The history further states: "After the removal of the ovaries, the patient began slowly to improve, mental symptoms gradually subsiding, and is able to attend to her household duties." Lawson Tait[36] gives notes on oophorectomy in ten cases for menstrual epilepsy and mania. In the five there was a complete arrest of the epilepsy and the mania was slowly disappearing. In the second, there was great relief. He gives also the case of a girl, seven years of age, who had suffered all her menstrual life with severe menstrual epilepsy. Lately this had assumed the additional character of acute mania at the periods. The patient was an inmate of the Binghampton Borough Asylum. She was with the consent of the commissioners placed under the care of Mr. Lawson Tait. Her ovaries were removed. The effect of the operation was an immediate and most marked improvement in her physical health, an entire absence of the mania, and a diminution of the fits from fifteen a month to three, with marked amelioration of the severity.

Similar cases have lately been reported as occurring at the Insane Asylum, at Norristown, Pa. One patient, in whom the first attacks of mania followed the birth of her child, 29 years previously, probably some sepsis then introduced. The attacks were always preceded by periods of severe pain in the right or left ovary. The ovaries and tubes were removed July 2, 1892, and in a little more than four weeks the patient went home, completely restored in body and mind. Another, where "the internal trouble dated from an abortion produced five years previously; the ovaries and tubes removed the same date as above, and on the 17th of September, 1892, the patient went home well, physically and mentally." Other cases, equally interesting, are given, all showing that pelvic disease may in some, so disturb the nervous system as to cause insanity, and that removing the diseased organs will relieve the physical sufferings of the patients, and, in many instances, restore them to mental health. Is there any reason why they should not be helped? I plead, in the interests of humanity, for these poor overburdened women.

COMMUNICATIONS.

CHLOROFORM ANÆSTHESIA AND ITS ADMINISTRATION.*

P. GUNTERMAN, M. D.

Means to subdue pain in operation have been used since the earliest days of medicine and surgery. Dioscoridis, 50 A. D., used a decoction of mandragora; others used the different kinds of narcotics; others used spirituous liquors and made their patients drunk. In 1844 Dr. Horace Wells, of Hartford, Conn., pulled a tooth for a patient under the influence of nitrous oxide, long before discovered by Sir Humprey Davy; in 1846, Dr. Morton, of Boston, did the same but used sulphuric ether as the anæsthetic; in the same year Dr. Warren, also of Boston, did the first surgical operation on a patient under the influence of ether. Sir. Jas. Simpson, in 1847, was the first to use chloroform. His brilliant success in this first and thousands of other cases soon established chloroform as the almost universal anæsthetic. It was by preference, used the world over except in the Eastern States of U. S. A. To this anæsthetic agent, "chloroform," if you will bear with me, I will call your attention to to-night.

In years gone by, it was necessary for the anæsthetist to make the test for purity of the article he was to use. His chloroform must be pure, i. e., it must be colorless; it must leave no odor or stain after evaporation; it must not discolor on being shaken with sulphhric acid and water; must not give chloride precipitation

36 *British Med. Jour.*, July 10, 1880.

* Read before Clinical Society, Louisville, April 4, 1893.

with nitrate of silver. To-day these tests are no longer necessary. All chemists can easily furnish the pure article and the only possible adulterant, alcohol, is absolutely harmless. I may be pardoned for making this short and imperfect resume of the history of anæsthetics in general and chloroform in particular, and we will now proceed with the main question at issue. In order to be more precise and permit an easy and quick survey, I will bring the subject under these four leading questions, viz:

1st. Who shall give chloroform?

2nd. To whom may and shall it be given?

3rd. How must it be given?

4th. How much is to be given and how does it effect the patient?

The first question, who shall give chloroform? In this age of specialties the supposition is near that I would unqualifiedly suggest a specialist, a man who makes it his business to give anæsthetics and gives this business his undivided attention. Not so. I maintain that every qualified physician ought to make it his business to be ready for the occasion and to be well versed in the details of anæsthetisation. No man who has not mastered these details, has the moral right to handle an agent at once so great and powerful for good or evil. One ought to think twice before he takes the balance of life of a fellow creature in hand, a scale so delicately poised, that the quiver of a muscle may sink the lethal side. Nor is this all. Every death that happens during the administration of chloroform is promptly ascribed to it. The clamoring mob abuses the unhappy administrator and, denouncing the agent as dangerous, robs many a poor sufferer of this great boon to humanity.

Rarely ought a doctor now-a-days be placed in a position to be anæsthetist and operator at the same time; yet all of us may be placed in this very unpleasant predicament. In such a case only the most urgent and absolute necessity can be at all excuse. The anæsthetist ought to give all his attention to his charge, and not for one moment ought he to attend to the operation, if he does he may find to his sorrow that the patient needs his attention no longer.

The next question is: To whom may and shall chloroform be given? Before we give chloroform to any one, he should be properly prepared, that is to say, his physical condition ought to be made as favorable for the taking of this powerful agent as can cenveniently be done. The person to be chloroformed ought not to have a full stomach, i. e., he ought not to have eaten solid food for at least six hours before he is to take chloroform. Nor is it well that the patient, perhaps nervous, excited or exhausted from illness and suffering becomes weak from prolonged fasting. It is, therefore, advisable to give a cup of broth or some fluid food a couple of hours preceding the administration of chloroform. Sometimes it is well to give stimulants.

The individuality of the patient is not so material. Chloroform may be given with impunity to the baby a few days old and to the centenerian. Babies and young children bear it remarkably well. The intermittent pulse is no contraindication.

Bright's disease, valvular disturbances of the heart, even fatty degeneration of that organ form no absolute barrier. However, it is well to inquire into all these possible conditions and, when present, should put us on our guard, make us all the more cautious and attentive. After the patient has fairly recovered from the influence of chloroform, it may be well to give some stimulant, sometimes a little morphine hypodermatically. This induces a few hours rest or sleep from which there is usually a refreshed awakening.

The question, how shall we give chloroform is one of vast importance. The first thing to decide is, by what means the agent is to be administered. Many an apparatus has been invented, Clover's, Snow's, etc., but none of them have stood the test of practical experience. If they were perfect dosimeters they were impracticable and unweildy, if they were manageable machines they had no intrinsic value save the maker's price, and did not better serve the purpose than the napkin and towels of Sir Jas. Simpson. Only in a regular operating room is a complicated apparatus practicable. Nothing is handier and better than a cone made of a napkin covered by paper. Such a cone answers every purpose. With it we can regulate the dose, the proper admixture of air and reduce waste by evaporation to a minimum.

Stand behind the patient at the head, notice the condition of countenance and pulse and place your finger, for convenience on the temporal artery. Encourage, reassure, cheer your patient and go to work. Pour in your cone about a drahm of chloroform, bring it gradually to the patient's face and let him breathe from the cone with a large allowance of air. Approach gradually and as soon as the sensibility of the air passages is overcome, as evinced by the subsidence of coughing or swallowing, give chloroform freely almost to the exclusion of air. Continue in this manner until your patient breathes easily and the eyelids no longer wink when touched. Now the patient is ready for most all operations. To bring him into this state takes from two to six minutes.

Your patients are your only care. Keep the finger on the pulse and watch with eye and ear the state of respiration. Be ready to state instantly rate and quality of pulse. If the patient's manner becomes excited withdraw the chloroform, if his countenance becomes livid give sparingly and much diluted, since often rapid and deep inspiration follow this state and enhance the danger by adding rapid anæsthesia to asphyxia. We must bear in mind the accumulative tendency of chloroform. Desist from giving chloroform when patient vomits, at least, if not sure that his stomach is empty and free from solid food. Be certain that your patient breathes and air enters into the lungs, diaphragmatic movements may deceive you. As soon as you hear larnygeal stertor stop your chloroform instanter.

The nature of the operation must determine how far your patient is to be anæsthetized. Watch unremittingly the sensibility of the conjunctiva and the condition of the pupil, whether or not it responds to light. If the pupil does not respond at all be extremely watchful and be ready to give timely warning, but be also careful to give no false alarm. In operations on the genito-urinary apparatus and on the rectum we find in the condition of the pupil the best indication whether the patient is sufficiently narcotized, he must be profoundly under the influence of chloroform. In case your patient becomes weak and faints as shown by pallor, profuse perspiration, and yawning leave off chloroform, and put him in the hyper recumbent posture with his head lower than his hips and order some stimulants. Quickly withdraw the chloroform when you perceive laryngeal stertor, pull the chin forward, upward and with it the head backward. This maneuvre removes (or may remove) the obstruction in the larynx and raises the ribs and sternum, in fact, is an easy and gentle form of artificial respiration. When this method does not succeed turn the patient on his side and institute artificial respiration after Marshall Hall or Silvester. It may become necessary to pull out the tongue which has fallen back and over the epiglottis. This ought to be done with a pair of sharp forceps, using a deal of force, to not say violence, in order to excite reflex action.

In extremely dangerous or disastrous cases quite a number of means for resuscitation are to be used to avert the fatal issue, but of these later on.

The last of our questions—how much is to be given and how does it effect the patient, remains to be answered. The quantity to be used in a given case depends on the nature of the operation and the probable time it takes to do it, and much more and perhaps wholly on the nature, temperament and habits of the individual. Nervous people, hysterical women and those addicted to the excessive use of liquor require a larger amount of chloroform than those who are differently or normally constituted. Children whilst they bear it well, require a great deal. I have seen patients thoroughly anæsthetized for two hours using only one ounce of chloroform whilst others in that length of time took as much as ten to twelve ounces. No two people, however, are affected alike. A person before an operation, let it be ever so trivial, is naturally somewhat nervous, shows signs of discomfort. Some are excited, pucker their mouths, pinch their eyes, screw and twist in all sorts of manner.

The first effect of anæsthesia is loss of this nervousness and restraint. The eyes are generally opened, the patient looks around and talks, often quite rationally, about the operation, etc. The conversation gradually becomes incoherent; often boisterous; some laugh and sing; some pray and curse. Now some muscular movements may be observed followed by a struggle requiring forcible restraint.

This is followed by a state of muscular rigidity which subsides gradually or abruptly. There is a little muttering succeeded by a drunken sleep with complete relaxation of all the voluntary muscles and abolition of sensibility. This is complete anæsthesia. Absence of sensibility in the conjunctiva and insensibility of the pupil to light give accurate information as to the true condition of the patient. Sometimes, more in children than in adults, the sphincters relax and the contents of the bowels and bladder are voided involuntarily. Such a state of affairs indicate some danger and solicit an extra degree of watchfulness lest the heart and respiratory muscles become involved in the same way.

Under the influence of chloroform the pulse becomes first accelerated, it gradually gets less frequent and finally resumes the normal tempo. It may become slow and weak as the operation progresses. The condition of the pulse may be greatly influenced by loss of blood during surgical procedure.

Pari passu with the pulse goes respiration. Respiration, too, first becomes quickened, gradually returns to normal (even, full and deep) and then may become superficial and shallow. As hinted before, movements of the chest are no assurance that respiration is properly going on, of which fact we can easily convince ourselves by listening, do not always trust to the eye alone.

You recollect the laryngeal stertor spoken of. There is another kind of stertor, the palatal stertor. Palatal stertor is no more nor less than ordinary snoring familiar to all. It is nearly always the warning signal that the patient is chloroformed enough. It is no sign of danger but marks the border line of safety. The laryngeal stertor with which we all have become acquainted in other conditions than those produced by anæsthesia is of the greatest moment. It is presumably, perhaps positively, demonstrated the result of closure of the larynx by paralysis of the epiglottis and a falling of the relaxed arytenoid folds on the rima glottis, and possibly a relaxed condition of the vocal cords. If this condition persist death from asphyxia is the inevitable result.

Death from chloroform either comes gradually or suddenly. Whatever may be the causes and how to counteract them we will not now discuss and reserve for some future day as a continuation.

Thanking you for your kind and patient attention, I cannot help being reminded of the Yankee's beaver, "he had to." Possibly you listened because you had to.

REPORT OF A REMARKABLE SERIES OF THIRTY-THREE CASES OF DIPHTHERIA TREATED BY THE TARTARIC ACID AND CORROSIVE SUBLIMATE OF MERCURY METHOD.*

M. GRAHAM TULL, A. M., M. D.,† PHILADELPHIA.

During the summer of 1889 my attention was attracted to an editorial in the *Medical News* which gave a synopsis of an article that had appeared a short time previously by Dr. Rennert, of Frankford-on the Main.

The substance of the article was to the effect that Rennert, while passing through an epidemic of diphtheria of great malignancy, and in which he had lost a great many cases, recollected that Laplace had but recently proved by direct experiment that corrosive sublimate in solution, slightly acidulated with tartaric acid was, by far, the most efficient of any of the germicides to be found, as applied to the bacteria of diphtheria.

Whereupon Rennert immediately changed his treatment. In addition to the conventional methods he had the throat thoroughly swabbed every six hours with a 1:500 tartaric acid corrosive sublimate solution, making sometimes four or five applications at one sitting. After instituting this procedure he did not lose a

*Read before the Philadelphia County Medical Society, April 26, 1893.

†Visiting Physician to the Baptist Orphanage.

patient, although the epidemic had not apparently begun to decrease in virulence.

I was at this time using as a disinfectant in obstetric work the so-called tartaric sublimate tablets of Mulford & Co., of Philadelphia, consisting of 3.85 grains of hydrarg. bichloride to 19.25 grains of tartaric acid. The addition of one of these tablets to four ounces of water makes a 1:500 solution. I, therefore, resolved to adopt Rennert's plan in future cases of diphtheria, as the rationalé of the method appealed very strongly to me.

It so happened that the following autumn I had from forty to fifty cases, and my experience fully corroborated the results of Dr. Rennert. I lost no cases treated by this method, although three children who had contracted the disease from my patients died of it. Two of these I saw after they had been ill a number of days, but they were then almost in articulo mortis. The third was a case of my own which did so well under this treatment, that the parents against my advice, persisted in their previously-formed intention of moving to another part of the city. The great distance debarred me from continuing in the case, and I subsequently learned of its death.

After this my cases were so few and scattered that, although the method proved eminently satisfactory, I kept no record of them.

During the autumn and winter of 1892, the following very interesting and, I trust, instructive series came under my observation at the Baptist Orphanage, of Philadelphia.

Late in the preceding winter two cases of diphtheria, in half grown children, appeared in a farm house directly opposite and distant about one hundred yards from the Orphanage. The disease presented a very malignant aspect, and, notwithstanding the faithful care of a competent brother practitioner, both children died after an illness of a week or ten days. A number of other cases appeared in the village at this time, one of which I happen to know resulted fatally.

The following August one of the boys at the Orphanage, a lad of sixteen years of age, who had been assisting the gardener spread manure that had been obtained from the farm where the children had died the preceding winter, was suddenly taken ill with fever, vomiting, and slight sore throat. My first visit being made at dusk, I fancied the case one of beginning scarlatina, of which we had had a few cases the preceding spring; but upon my visit the following morning the diagnosis of diphtheria was apparent, and I lost no time in having him transferred to the Municipal Hospital, dreading the entrance of the disease among so many children.

Unfortunately, we were too late, and in the next few days nine of the boys from the same cottage developed well-marked cases and were at once isolated in a separate building which had been converted into a temporary infirmary. A trained nurse was obtained and the child placed under treatment at once. As a routine measure, each child was given the following tablet-triturate: hydrarg. chlor. mit., gr. one-fifth; sodii bicarb., gr. j; ipecac, gr. one-tenth; every half hour until free movements of the bowel ensued, and after that they were continued every two hours. The following mixture modified to suit the varying ages, was also employed: ℞. —Quininæ sulph., potas. chlorat., potas. citrat., syr. ferri chlor. (P. D. & Co.), syr. yerba santa.—M. et Sig., one drachm every two hours.

The nourishment consisted of liq. peptones (S. & J.) and milk at the commencement of the cases, rapidly followed by a full diet as the patient convalesced. In addition to this the nurse was instructed to apply every three hours by means of a cotton swab, a 1:500 solution of the tartaric acid corrosive sublimate tablet, made by dissolving one of Mulford's tablets in a gill of water.

The results were immediate and remarkable, the temperature falling, the pulse becoming normal, and the aspect of the child undergoing an astonishing change. The course of the membrane across the fauces was checked, and in each case came away in about forty-eight hours. All of these children were practically well in two days while the first case, which was transferred to the Municipal Hospital, was quite seriously ill for some time, and was not discharged for over six weeks.

The effect of this unusual success in the first nine cases was, in some respects, followed by unpleasant results, though of great value to this paper, furnishing, as it

does, complete check experiments upon my other cases.

A feeling of skepticism was developed in the minds of the attendants, and even the nurse was tainted by the prevailing feeling. So that, after the children first affected were about ready to return to their cottages, being allowed to play on the veranda on pleasant days, the strict quarantine which I had endeavored to establish was completely relaxed, and visits of more or less ceremony were exchanged between the nurse and the matrons of the other cottages.

I had promised to return the children to their own building on Wednesday, but on the Friday preceding five of the children in the so-called children's cottages were taken ill with fever, vomiting, coated tongues, etc., not, however, complaining of their throats.

The matron of their cottage, who was a law unto herself, said: "The doctor was mistaken in thinking that the children who were sick had had diphtheria and, that she would not allow her little ones to be taken to the infirmary, but would show him that she could treat them as well as he." She, therefore, had them taken to the third story of her building, and allowed the well to stay with and amuse the sick. This was, of course, in direct opposition to my order that any child with the slightest suspicious symptoms should be sent immediately to the infirmary, where we had provided a separate apartment for such cases.

The first child was taken ill on Friday, and on Monday evening, after what I had hoped would be my last visit to the infirmary, the matron stopped me to say that she had five children ill with a slight stomach derangement, assuring me at the same time that there was nothing wrong with the throats, as she had carefully examined them. I declined to see them then, having just left a diphtheritic atmosphere, but called the next afternoon, having been prevented from going earlier, owing to urgent professional engagements. To my horror and disgust I found the children had had diphtheria for some days, their sickness having been carefully concealed from me. They were at once removed to proper quarters, but the disease had acquired such headway that in four or five days three of the five died, all of them dying of heart and kidney involvement, being victims, in my opinion of the development and absorption of the diphtheritic ptomaine. After this fresh outbreak we had eighteen other cases, two of whom died. One a child two years old with a very bad family history, all of his family connection being dead, and the other a child four years old, also with a bad family history, who at the height of the diphtheria developed a very violent attack of measles and succumbed to the combined force of the two diseases.

I have only been able to get the charts of the first nine cases, which I here append:

CASE. I.—George T., aged eleven years, entered the infirmary on September 5, 1892. Temperature on entering at 6 P. M. 102°; pulse 120. At 8 P. M. after swabbing, temperature 100.8°; pulse, 100. September 6th, 11 A. M., Temperature, 101°; pulse, 99. 11 P. M. Temperature, 99.4°; pulse, 80. September 7th, 2 A. M. Temperature 98.4°; pulse 84. The diphtheritic patch disappeared. Uninterrupted recovery.

CASE II.—Harry McK., aged ten years, admitted September 4th, 6 P. M. Temperature 98.8°; pulse, 84; throat very much inflamed, but no patch. 5th inst. Throat considerably ulcerated. 8 A. M. Pulse, 80; temperature, 98.6°. 6th inst., 5 A. M. Pulse 69; temperature, 98.4°. Patch disappeared. Uninterrupted recovery.

CASE III.—Thomas H., aged ten years, admitted August 27, 1892, 4.30 P. M. Pulse, 105; temperature 101°. 10 P. M. Pulse 110; temperature, 102.6°. Throat with large, dark patch. Treatment continued through the night, and recorded every two hours. August 28th 12 M. Pulse, 90; temperature, 98.4. 6 P. M. Pulse, 84; temperature, 99.4°. 9 P. M. Pulse, 84; temperature, 98°. 12, midnight, Pulse, 86; temperature, 98.4°. Ulcerated condition disappeared on 28th inst. Uninterrupted recovery.

CASE IV.—Fred D., aged nine years, admitted August 30th, 4 p. m. Pulse, 105; temperature, 104°. 7 P. M. Temperature, 103. 10 P. M. Temperature, 100.6°. 31st inst. Temperature, 99.2°. September 1st, 1 A. M. Temperature, 98.8°. 1 P. M. Temperature, 98.4°; pulse, 80. In this case on entering he had offensive breath, large patch extending back on the fauces, coated tongue, flushed face, bad headache, etc. Recovery was uninterrupted.

CASE V.—Elmer G., aged eight years, admitted August 31st, 2 P. M. Face flushed, throat badly ulcerated, extending upon the fauces. Pulse, 103; temperature, 101.6°. 5 P. M., temperature, 101.4°; 8 P. M., 100.4°; 11 P. M., 100°. September 1st, 2 A. M., temperature, 99.8°; 5 A. M., 99.8°; 2 P. M., 99.4°; 11 P. M., 98.6°. September 2d, 2 A. M., temperature, 98.4°. Uninterrupted recovery.

CASE VI.—Roland S., aged seven years, admitted August 31st. Patch large and extended. Breath very offensive. Glands on left side enlarged. 11 A. M. Pulse, 116; temperature, 102.2°. 2 P. M. Temperature, 103.6°; 5 P. M., 102°; 8 P. M., 101.2°; 11 P. M., 100°. September 1st, 2 A. M. Temperature, 98.8°; 11 A. M., 102°; 2 P. M., 99°; 8 P. M., 98.4°. Uninterrupted recovery.

CASE VII.—Thomas C., aged twelve years, admitted September 3d. 5 P. M. Temperature, 102°; 8. P. M., 103°; 11 P. M., 102°. 4th inst., 2 A. M. Temperature, 102.2°; 5 A. M., 100°; 8 A. M., 100°; 11 A. M., 99.4°; 2 P. M., 98.6°. 5th inst., 2 A. M., 98.4°. Recovery uninterrupted.

CASE VIII.—Willie H., admitted August 27th.

Diphtheritic patch large. Cervical glands very much swollen. Temperature, 7 P. M., 99.6°. Ranged below this until the 29th inst., when at 4 P. M. it fell to 98.4°, and remained so. Recovery uninterrupted.

CASE IX.—Charles W., admitted September 10th. 5 P. M. Temperature, 102.2°. Throat involvement marked. 8 P. M. Temperature fell to 98.6°. 11th inst., as 8 P. M. was 98.4°, and remained so. Recovery uninterrupted.

With the exception of those who died the other cases all presented this same clinical picture. In some of the fatal cases I was obliged to use a spray of hydrogen peroxide in addition to the bichloride to purify the air, on account of the intensely disagreeable odor, but my experience with it as a remedial agent has been so unsatisfactory as compared with the bichloride that I rarely use it, excepting as a deodorizer. The danger of salivation from the sublimate solution seems to be nil, as in a few laryngeal cases I have given as much as the eighth of a grain every two hours in addition to the local use, although in such cases I think the drug should be carefully watched. Nor is there any danger from the patient swallowing the cotton, as in one instant a patient of mine did, owing to the cotton being so carelessly rolled on the holder that it come off in the child's mouth and was swallowed. Even in this case the dose of the bichloride is not excessive. A drachm of the solution only contains one-eighth of a grain, and as the ordinary tuft of cotton used for such purposes will only hold a teaspoonful of the solution, and almost all of that is expressed out of the cotton against the fauces, and expectorated, the amount swallowed is not more than a tonic dose.

The advantages of this method are many, and the rationalé of it appeals very strongly the judgment.

We all recognize the fact that the diphtheritic germ is not markedly aggressive, and we know that a necessary concomitant to its spread is a proper culture field. By experience we have learned that the throat of a delicate child furnishes a good culture medium, while that of a robust child will fight it off successfully. Therefore, anything that detracts from the value of the throat as a culture medium adds to the natural resisting power of the susceptible child and raises him to the level of the child of stronger constitution, who needs no extraneous aid. This desideratum is obtained when we have a wash which, though deadly to the germ, is practically harmless to the child. Then, by the death of the bacteria, the membrane is limited and the danger of subsequent mechanical obstruction is obviated. In destroying the germ we also cause a cessation in the formation and absorption of the ptomaines, thus lessening the risk of paralysis, septicæmia, heart failure, albuminuria, and all the train of symptoms that follow in the wake of this powerful animal alkaloid. Another advantage is that the treatment is quite as satisfactory in the treatment of the less serious throat and tonsillar affections. I have found nothing act so rapidly and certainly in simple ulcerative tonsilitis or in the follicular variety, the subjective symptoms in both yielding at once. Then, again, it lessens the chances of the spread of the disease through a house or neighborhood, and reduces to a minimum the danger to the attending physician, as the disinfection is carried out at the very fountain head of the trouble. Instead of hunting the germs in the nooks and crannies of a room, they are attacked in their own citadel.

And still another advantage in this method of treatment is that no time is lost, as the necessary tablets furnish a part of the physician's obstetric armamentarium. It is my practice to at once give the attendant of my patient a tablet, with minute instructions as to how to apply the wash. My experience has taught me that a good method is to make the applications every three hours, and to simply press the cotton against the membrane, thus soaking it. The second or third day the membrane becomes readily detachable, and usually comes away on withdrawing the cotton. Formerly I thought it necessary to rub and tear the membrane loose, but I have never seen any benefit from it, while it is very annoying to the patient. As the patient begins to convalesce I make the intervals of application six hours, and, finally, twelve hours apart. While my results have been generally obtained by means of the cotton applicator I can see no reason why the atomizer should be interdicted, although in an unruly child it is almost as difficult to use one method as the other.

In conclusion, I claim for the method that, in competent hands, such as Dr. Rennert's, and under the peculiar circumstances in which a perfect check experi-

ment was furnished, such as in my own cases, it has proved a simple and perfectly satisfactory remedial agent, and I beg for it a thorough trial, hoping that it may prove in the hands of others all that I have obtained from it.

POINTS OF SIMILARITY BETWEEN US AND HOMŒOPATHIC PHYSICIANS.

The Annual Address of the President of Philadelphia County Medical Society, Read May 24, 1893.

JOHN B. ROBERTS, A. M., M. D.

In the address which I had the honor of delivering from the Presidential chair a year ago, I gave it as my opinion that this Society should be liberal enough to accept as a member any physician whose education and personal character made him a fit associate for intelligent men. I stated my belief that the test of qualification for membership should not be the college from which the applicant received his diploma; but an education enabling him to understand and appreciate the science of medicine, and an honest purpose to treat his patients by all means and methods, which experience, investigation and research show to be serviceable. It seemed to me then, as it does now, that such a physician's political, religious or social beliefs should not disqualify him; nor his opinion that in "similars" he sometimes finds a remedy of value.

Following out this line of thought, I have undertaken an investigation to determine whether there are any points of similarity between us, who decline to receive any sectarian designation, and those who accept for themselves the name of homœopathic physician. This study has interested me very much, and it is my purpose to lay some of the results before the Society this evening.

None will deny the fact that as a class we, as well as they, are law-abiding citizens, whose culture, intelligence and wealth add to the intellectual and financial prosperity of the districts in which we live. The doctors of village, town or city, are ever respected by the community, and their counsel is sought in many emergencies not strictly medical. This deferential courtesy is extended to all honorable and skilful physicians, without thought as to their belief in, or rejection of, the law of similars. In this amenity of civilized society, then, there exists no difference between us and our homœopathic neighbors. Our mutual social relations also teach us that there should be none. We meet each other in drawing-room, mart, or amusement hall, to find no difference in courtesy, refinement or large-hearted charity. How often do we meet a homœopathic friend with the heartiest of handshakes, because we honor him as a man and love him as a friend. The grasp returned shows that the respect and affection are fully reciprocated.

Much to be regretted is it that a marked similarity exists between the ignorant and half-educated graduate of all kinds of medical colleges. We do not hold a monopoly in the graduation of men who tell State Boards of Medical Examiners that the boiling-point of Fahrenheit is "about 300°;" that the "average respirations are 70 per minute," and that the same disease is called pneumonia when it affects one lung, pleurisy when it affects the other. The ignorant and reckless doctor will always be a menace to the public health, whether he decline or accept the designation "homœopathic." The greater damage is probably done by our half-educated graduates, because the number of homœopathic medical colleges in Canada and the United States is only 26, whereas we have 220. From these colleges there graduated, in 1890, only 391 homœopathic physicians, while our own colleges sent out 4237. The number of medical matriculates in the United States and Canada during the decade between 1880 to 1890 was, in our own colleges, 115,355. The number of graduates was 36,655. The number of

matriculates in the homœopathic colleges in the same decade was 11,366; the number of graduates, 3,883. The percentage of graduates to matriculates in our schools was 30.9; in the homœopathic schools, 24.1. These tables, taken from the statistics compiled by the Illinois State Board of Health,[1] would seem to show that the ratio between the number of students and the persons granted degrees was nearly the same in both classes of medical colleges.

As many medical colleges are commercial associations to manufacture doctors as rapidly and cheaply as possible, it is apparent that their output will be ignorant physicians, whose individual beliefs as to the laws or methods of therapeutics will do little to protect the public from malpractice and criminal medical ignorance. The high-grade medical colleges have recognized the fact that the cure for this public wrong is the establishment of State Boards of Medical Examiners, whose examination alone shall determine the qualifications of the applicant for license to practise. It is gratifying to know that we and the most highly educated homœopathic physicians in the various States agree on the necessity of such State laws. It is true, however, that a number of our medical schools (University of Pennsylvania, University of Michigan, Harvard University, Woman's Medical College of Pennsylvania, and perhaps one or two others) now require four annual courses of college lectures before the student can obtain his degree; and that only one homœopathic college (Boston University School of Medicine), so far as I know, demands this high standard. It is to be hoped that more colleges will soon follow this movement to elevate the standard of medical education.

The text book for students recommended in official announcements afford instructive evidence of the similarity in teaching given the four or five thousand graduates coming annually from the two kinds of medical colleges. The announcements of the Hahnemann Medical College of Philadelphia, for 1891–92 shows that a great proportion of the works recommended are the same as those we advise our students to purchase. Leidy's *Anatomy*, Tyson's *Urinary Analysis*, *United States Pharmacopœia*, Mann's *Prescription-Writing*, the Stillé and Maisch *Dispensatory*, Wood's *Therapeutics*, Pepper's *System of Medicine*, Gross's *Surgery*, Agnew's *Surgery*, Playfair's *Obstetrics*, Duhring on *Diseases of the Skin*, Reese's *Medical Jurisprudence*, and Gould's *Dictionary* occupy no less conspicuous positions in the list there found than in the announcements of our own colleges.

What I have said shows clearly enough that the material out of which medical students are made, and the college training by which they are developed into medical practitioners are very similar, whether the intending doctor expects to become a physician without sectarian title or hopes to belong to the ranks of homœopathic medicine. The students are gentle or boorish, earnest or slothful, intelligent or dull, ignorant or wise, in about the same proportion. They study many of the same books, live in the same boarding-houses, have the same pleasures and trials, and make much the same kind of doctors. The educated, true and earnest are capable of bringing manifold blessings into the sick room; the ignorant, false and careless do infinite harm to the public—the public which, in Pennsylvania, has no protection from such dangers, since the State has not as yet thought it worth while to weed out the grossly ignorant and incompetent by a state examination and license.

A very striking similarity between us and our homœopathic neighbors is the latitude of opinion exercised in the choice and administration of drugs. Many thoughtless persons believe that we give only large doses, the homœopaths only small ones; that we do not use powders or triturates, that they do not write prescriptions, or administer alcohol or opium. Nothing is easier than to show the fallacy of these statements.

Every member of this Society knows that any attempt to restrict one of us to the use of certain medicines or methods of treatment, or to the employment of any stated size of dose, would result in the immmediate rupture and destruction of the Society. Such interference with individual liberty would not be tolerated. Everything and anything that I believe will aid my patient I must have full liberty to use. No organization has the

1 Medical Education, etc., Springfield, 1891, pp. 24 and 31.

right to say what drug or what medicinal dose you or I shall employ in the treatment of disease. The whole field of science, medical and collateral, is utilized in our endeavor to relieve and cure disease. We are bound by no therapeutic law of "similars," or of "dissimilars;" we never have been and never can be. We follow the authority of no man, and are bound by no dogmas; but with full liberty of conscience we act as individuals responsible to no other human agent. This phase of our position is often misunderstood by the public. It was, however, clearly stated ten or a dozen years ago in the deliberately written words of the American Medical Association, which, in speaking of a similar topic, said: "Neither is there any other article or clause of the said Code of Ethics that interferes with the exercise of the most perfect liberty of individual opinion and practice."[1]

The homœopathic practitioner of to-day, as a rule, feels the same liberty as we do, but believes what he calls the "law of similars" being a good indication as to the choice of remedies.

Neither we nor they, unless it be isolated individuals, base our practice on "an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

If the action of homœopathic medical societies, of homœopathic medical journals, and the spoken and written statements of homœopathic physicians are examined, it is evident that very many of those whom the public regards as homœopathists have comparatively little faith in the infinitesimal doses of Hahnemann, or in the infallibility or universality of his law. The gentlemen represented in or by these societies, journals and statements have, it would seem, a belief in the more or less frequent value of the "law of similars" in treating disease; but admit that cases, more or less frequently, require the doctor to use non-homœopathic methods if he is conscientiously to do the best thing possible for his patient. In the words of a resolution passed by the Homœopathic Medical Society of the County of New York, on February 8, 1878, the belief in the law of similars "does not debar us [homœopathic physicians] from recognizing and making use of the results of any experience, and we shall exercise and defend the inviolable right of every educated physician to make practical use of any established principle of medical science, or of any therapeutic facts founded on experiments and verified by experience, so far as his individual judgment they shall tend to promote the welfare of those under his professional care."[1] This statement corresponds with the attitude and practice of us who, as non-sectarians, believe in the science and art of medicine; and would render the subscribers to it eligible for membership in the American Medical Association, the Medical Society of the State of Pennsylvania, or the Philadelphia County Medical Society.

Dr. Joseph Kidd and Dr. W. H. Holcombe, well-known homœopathic writers, believe, with the members of the New York Homœopathic Society, that everything and every method which cures should be utilized, even by those believing in the law of similars as a valuable indication in therapeutics. Dr. Holcombe says a physician professing belief in the homœopathic law is not obliged to limit his practice strictly to the application of that law, but claims everything which cures. Dr. Kidd, who held a position in the London Homœopathic College, made a similar statement.

I think I am justified in the statement that to-day there is comparatively little belief in, or practice of homœopathy as advocated by Hahnemann. There is no doubt that a few homœopathists, represented by Dr. Berridge, the late Dr. Lippe and Dr. Neidhard, believe, or at least did believe, in the infinitesimal doses of Hahnemann and the universality of his law of similars, the truth of which two points is, according to Neidhard,[2] "identical;" but I am inclined to think that the great majority of physicians considering themselves homœopathists reject the idea that diminishing the dose increases the power of any drug. Of those all, or nearly all, give only a modified assent to the law of similars; believing that it is often, perhaps

1 See Journal of American Medical Association, Nov. 19, 1892, p. 611.

1. This quotation is extracted from a criticism of the resolution, contained in a "Declaration of Homœopathic Principles," published in *The Organon*, Liverpool, April, 1878.

2. *Universality of the Homœopathic Law of Cure*, pp. 29–34.

very often, a good rule to follow in selecting a remedy, but that many diseased conditions are best treated by remedies not selected in a homœopathic way. Very many quotations could be made to support my position.

It seems to me that the physicians recognized by the public as homœopaths consists of two classes: First, a small number who adhere to Hahnemann's teachings, which seem to me to be not founded on good evidence, and therefore unscientific and unworthy of credence. Secondly, an increasingly large number who, while entirely rejecting the doctrine of increased power being given drugs by dilution, still have some belief in the law of similars. These last do not wholly rely upon the homœopathic law or methods in treating disease as presented to them in daily practice. It is probable that in many cases a drug originally suggested for a certain disease by a homœopathic text-book or authority is used when that condition is to be treated, without much thought being given to the law; though the drug is administered in powder or pellets, or in a tumbler of water. If this be true, it corresponds with the practice of many of us non-sectarian physicians, who use powders, small pills and solutions advocated by well-known authors and teachers without pausing to inquire the reason for our faith in, and use of, them.

Many homœopathic physicians have their libraries well stocked with journals and text-books, edited and written by non-sectarian physicians, who, of course, repudiate Hahnemann's teachings. Various remedies are advocated in these works for the diseases which doctors are called upon to treat. It seems to me probable that homœopaths consult these books in their libraries and select from the drugs therein recommended such as seem to them to be instances conforming to the law of similars. My opinion is confirmed by a recent review in a homœopathic journal,[1] of a book written by a non-sectarian physician. It says of the book: "The doses are generally larger than would be called for, but the suggestive character of the prescriptions will often give excellent hints to meet individual cases." This is very far from being the practice of homœopathy as Hahnemann taught it; but it is not unlike scientific medicine, which aims to select such remedies as will correct these morbid disturbances and changes in the organs and tissues which are the essence of the disease. In a similar manner many of the text-books used in homœopathic medical colleges are written by those who deny the truth of homœopathy.

Dr. James B. Bell, President of the Hahnemannian Association, in his address last June, said:[2] "Our society numbers in active living members about 150, and it would be a generous estimate, I think, to double that number, as representing in the whole world all those who may be called true Hahnemannians or who are becoming such. If we have patients going to other cities, especially in the West and South, how rarely can we recommend a physician to them, and if the patients are taken to Europe or England, we know of but five or six men in the great cities to whom we can safely intrust them."

Such a statement, coming from an evidently reliable homœopathic source, convinces me that the great majority of homœopathic physicians are very like ourselves in their means and methods of treating disease.

We believe with Rokitansky, that the basis of medical treatment is a knowledge of the morbid disturbances and changes in the tissues and organs. The real homœopathy, if I read Hahnemann and his followers aright, pays no attention to the microscopical and chemical changes in tissues and organs, but believes in selecting a remedy which by "provings" causes symptoms similar to, but not identical with, "the totality of the symptoms seen in the patient."

The great body, then, of homœopathic practitioners, if Dr. Bell is correct, use any drug, administered in any way that seems to them likely to be beneficial. They are, however, called homœopaths, because they have a belief in the partial value of a law of similars, and because non-sectarian physicians usually decline medical association with them. All of these physicians ought to be accepted by us as eligible for professional association and consultation, since they are willing to use any and all methods, and are bound by no exclusive dogma or law. Their preference for remedies selected according to what they consider a good rule in many

1. *N. Y. Medical Times*, January, 1892, p. 309.

2. *The Homœopathic Physician*, Philadelphia, August, 1892.

cases does not impeach their general intelligence or their value to the community any more than the differing opinions of many in our own ranks on other medical topics.

That the tendency of hemœopaths is to drop Hahnemann's views and come nearer and nearer to scientific medicine, is well shown in a recent work of Professor Theodor Bakody, a homœopathist of Buda-Pesth.[1] He says: "The dilution of medicine should not be carried to a point beyond scientific recognition;" and "I do not consider the biological medical therapeutics of Hahnemann a universal one, inasmuch as it covers only that department of practical activity where medicinal therapeutic causal cures can be effected." These views were expressed by him in 1873, and were still his views when the volume was written. A further quotation will show how near he is coming to our views in medicine. "In making drug-provings we should not be satisfied with the manifestations of mere subjective or general functional symptoms, but in accordance with the scientific knowledge of our day also include in the field of our observations the finer pathological, physiological, anatomical, and chemical manifestations."

This method of finding out the action of drugs is indeed scientific, and different from the method of Hahnemann, his immediate followers and present imitators. Compare, for example, Hahnemann's *Materia Medica Pura*, translated by R. E. Dudgeon, M. D., with annotations by Richard Hughes, L.R.C.P.E., Liverpool, 1880.

An indirect evidence of this decadence of belief in Hahnemann's homœopathy is the effort of many homœopaths to explain away the inconsistency of their practice with homœopathic doctrines. Dr. Charles S. Mack, of Ann Arbor, affords curious corroboration on this point.[2] He says that the homœopathic law of similars is "the law and the only possible law of cure," but that there are various principles "upon which useful, though not curative, treatment may be based." He says that iron, lime, demulcent drinks, stimulants, and germ-destroying agents may be useful though not homœopathically indicated, and may lead to the recovery of the patient. This, however, he regards as not a cure but a recovery. It is difficult for me to see the difference as far as the patient is concerned, even though Dr. Mack says (p. 75) that he finds "no impropriety in limiting the meaning which *cure* shall have while considering the claim of similia." In other words, he justifies his belief in the homœopathic law of similia as the *only curative* treatment of disease, by excluding all cases of patients who recover under non-homœopathic methods of treatment. The latter *recover* but are not *cured*. When asked if he would use a chemical antidote to a chemical poison, which was found to be the cause of the acute disease from which the patient was suffering, he replies that he would use such an antidote, but that "even successful treatment with that antidote would not be curative" (p. 123). His faith in the homœopathic law is thus seen to be founded on a hair-splitting of words; and he further says (p. 135), "today homœopathists are, more than formerly, availing themselves of various practices which are distinctly not homœopathy."

Recent publications in the homœopathic journals indicate the same half-hearted belief in the "law of similars," and the almost total rejection of the doctrine of infinitesimal doses.

Dr. D. A. Gorton, a homœopath not unknown to homœpathists, deprecates[1] the use of the words "System of Medicine" as applied to homœopathy. He says it is only a system of therapeutics, and states that he is constrained to regard the law of similars as but a fragment in the grand art of curing disease. He thinks that Hahnemann was wrong in regarding homœopathy as destined to supplant all other methods of treatment. He quotes from Hahnemann's *Organon* to show that a true homœopath must never give a laxative, prescribe a warm bath, nor subdue pain with opium; and indicates his belief that few homœopathic physicians are, therefore, true homœopathists in Hahnemann's sense. He expresses doubt whether, out of the eighty or more homœopathic physicians in Brooklyn, twenty could be found capable

1 Scientific Medicine in its Relation to Homœopathy. Translated by R. F. Bauer, M. D., 1891, pp. 36, 37.

2 Philosophy in Homœopathy, Chicago, 1890.

1 The Drift of Medical Philosophy, revised edition, 1875, pp. 56 and 70.

of rendering in a chronic disease or in an obscure acute disease, a sound prescription according to the law of similars (p. 61). He adds (p. 65) that he has known many professedly strict homœopathic physicians to break up ague paroxysms with massive doses of quinine, use caustics in ulcers, and prescribe emetics, cathartics and sudorifics.

I am quite sure that my hearers will agree with me that we are very like homœopaths in the treatment of disease, if these homœopathic writers give a truthful account of the methods employed by themselves and their colleagues. These statements, moreover, are substantiated by other writers, who speak in a similar strain.

A well-known journal,[1] edited by believers in homœopathy, in a recent editorial made the following statement: "It is apparent to even the casual observer, that scientific study is rapidly bringing all schools more in harmony with each other, and while it eliminates, more and more the theoretical and conjectural, is building up a scientific therapeutics based upon the unanswerable logic of facts, the general outline of which will be acceptable to all."

The same journal suggests (p. 51) that if the societies composed of non-sectarian physicians revise their by-laws so that physicians now called homœopaths may be eligible for membership, the next move should be for the homœopathic medical societies to drop the sectarian name. Could anything show better than this suggestion the slight hold homœopathy has upon many of the supposed followers of Samuel Hahnemann?

The *Northwestern Journal of Homœopathy* says: "The practitioners of homœopathy forty years ago who are now living can scarcely recognize the merchantable article called homœopathy at the present day,"[2] and asserts that the doctors who "really practice homœopathy are very few compared with the proportions who did so forty years ago."

The *Homœopathic News* for March, 1892, says editorially: "We venture to assert that had not our school drifted away from the practice of forty years ago, it would have been dead and buried long since." Continuing, this recognized journal of homœopathy says:

"We have drifted away from the practice of giving a pellet of the two-hundredth or higher, and waiting thirty or sixty days for its curative effects; from the prescribing of a high dilution by smelling the dry pellets, those same pellets 'grafted' by shaking a thousand pure pellets with one medicated by the ten-thousandth.

"We have drifted away from a belief in provings made by taking a single dose of the one-thousandth, thirtieth, or third even, and then recording all the symptoms felt by the power—natural symptoms, colds, diarrhœa, etc., for the next sixty days!

"We have drifted away from the carrying a pocket repertory to the bedside of the patient, and recording the symptoms in columns, and a weary search in said repertory until a mechanical similimum was found.

"We have drifted away from the days when our pseudo-surgery was a disgraceful farce, when we expected silica to open a felon, or hepar sulphur to lance an abscess.

"We have drifted away from the narration of miraculous cures with the highest attenuations, which are not cures at all, but a spontaneous finale of a self-limited disease.

"We have drifted away from the days when our practitioners would sit by the bedside of a woman dying of uterine hemorrhage, hunting in a repertory for the 'indicated remedy,' while the vital fluid was ebbing away, without recourse to the tampon or ergot."

Dr. Conrad Wasselhoeft, in a paper read before the Southern Homœopathic Medical Association,[1] admits that homœopathists, in order to join the ranks of a united medical profession, may "have to recede somewhat from the too premature axiom of the universality and infallability of our law of similars." He apparently signifies his assent to this necessity.

In an article on "Defects and Limitations of the Materia Medica Homoeopathica," a writer, who is a homoepathist, discusses[2] the difficulty of selecting the proper remedy, because of the possibility

1 *New York Medical Times*, May, 1892, p. 48.

2 Reprinted in *New York Medical Times*, May, 1892, p. 55.

1 *New York Medical Times*, January, 1892, p. 313.

2 *New York Medical Times*, November, 1891, p. 225.

of the patient not detailing symptoms accurately, and of the inaccuracy of some of the drug effects attributed to remedies. He makes this pertinent statement:

"It is not too much to say that clinical experience does not verify the half of the symptoms to be found in Allen's mammoth collation of materia medica, and, like the man who never speaks but half the truth, one is left to wonder which half of the recorded symptoms is true and which is false. Many of the prominent drugs in the materia medica were proved, as our correspondent says, in the thirtieth potency—that is to say, in the decillionth dilution. What manner of man must he be who can believe that there is an atom of a drug in a drop of that dilution, or the least degree of drug-force!"

The unreliability of homoeopathic "provings" and of the derived "pathogenesy" of drugs is here admitted even by a believer in the law of similars. The *Hahnemannian Monthly*, whose homoeopathic orthodoxy will, I presume, not be impeached, publishes an article[1] by Dr. J. P. Dake, in which the author says: "But the reliability of pathogenesy has not suffered alone from such causes. Some drug-provers have undertaken to note symptoms produced by doses in which there was no probability, hardly a possibility, of the least drug influences; and some have passed by a great number of articles, having promise of medicinal power and usefulness, to prove some that are eminently disgusting as well as useless."

Even Charles Neidhard has written: "For some peculiar diseases the homoeopathic law requires us to give large doses."[2]

This rather lengthy series of quotations from homoeopathic writers has been made to establish my point that we and most of them are for all practical purposes similar and at one. They, as well as we, are free to choose whatsoever is thought to be the proper remedy for a diseased condition, and to give it in whatsoever dose is considered curative. Speculation as to the manner of action of a remedy or the best method of selecting it is only interesting from a philosophical point of view. Difference of opinion in such matters makes us no less like them than it makes me different from such members of this Society as believe pulmonary consumption to be of nervous origin, or from those who consider aseptic trephining a dangerous operation.

Another point of similarity between the members of the Philadelphia County Medical Society and the homœopathic practitioners of this city and State is, that much attention is given by both to hygienic and dietetic measures in the management and treatment of the sick. The value of a faithful study of these departments of medical science is admitted by all intelligent practitioners. Again, all of us believe that much priceless information has been gained by investigations into the effects of drugs upon the healthy human organism. That the results of such study can be utilized in the treatment of disease is averred by writers such as Wood, Bartholow, and Hare in our ranks, and by the homœopathic authorities, Dake, Farrington, and Hughes.

When our patients are suffering from symptoms which cannot be removed by any known means, or from diseases which experience has shown to be at present incurable, we and they resort to palliative measures. Remedies which lessen suffering and prolong life, even if they have not the least curative effect on the symptoms or disease, are often administered by you and me and our homœopathic neighbor. Opium, one of the most conspicuous of these drugs, is alike used by us all; and by the way, serves well to illustrate the fact that even homœopathists do not adhere rigidly to their supposed custom of administering remedies singly. It, as we all know, is a combination of many valuable remedies.

A glance at the catalogues of Boericke & Tafel, known the country over as manufacturers of homœopathic remedies, will prove to you that my statements are well founded. In them are seen price-lists of triturates of opium (1x, 2x, 3x, and 6x); sepia (2x, 3x, and 6x), mercurius vivus, silicea, morphium, graphites, and china, as well as of iodoform, podophyllin, rheum, and other names more familiar to our ears. It is more than probable that these chemists supply physicians of all kinds with these triturates, as well as with their one-drop tablets (made from mother

2 Universality of the Homœopathic Law of Cure, second edition, p. 30.

tincture) of byronia alba, aconite, senna, and squill.

When Charles J. Semple wrote, in 1874,[1] that constipation was to be treated by rhubarb and Seidlitz powder and advocated the use of morphine in colic, he certainly was not dissimilar from us in this respect, nor we from him. Yet he was a pronounced homœopathist.

I have already indicated by quotations from homœopathic sources that few homœopathic practitioners now believe in the augmentation of the medicinal power of a drug by diminishing the quantity administered. Hahnemann's assertion of the increasing potency of these infinitesimal doses seems to have lost its supporters among homœopathic practitioners. It is needless to say that in this disbelief we are like them.

The study which resulted in the production of this address has brought me to the same conclusion as that indicated by Dr. Henry O. Marcy, the recent President of the American Medical Association. He says[1] that "Homœopathy was born, in a measure, as a protest to indiscriminate heroic dosing with powerful drugs," and its popular success was partly due to "an unreasoning prejudice in the minds of a narrow conservative leadership" which characterized our predecessors. He intimates that we and the average homœopathic physician are so nearly alike, except in name, that the great body politic of our profession should institute measures to make it easy for such men properly educated to enlist in the grand army of workers devoted to unbiased investigation and the practice of scientific medicine.

Dr. Henry I. Bowditch, our distinguished associate, put it even more strongly when he wrote,[2] not many years since, that homœopathy and eclecticism were the legitimate offspring of the absurdities of the medical profession at the time of their advent.

A short time ago a paper on revision of the By-laws of the American Medical Association was read before the Chicago Medical Society by Dr. J. C. Culbertson, the well-known editor of the *Journal* of Association. The action of the Society in approving the sentiment of the paper indicates that its members share the views of President Marcy and Dr. Culbertson; for the first important clause of the proposed revised By-laws provides that the members of the American Medical Association "shall be physicians in good standing in the medical profession, who are graduates of reputable medical colleges, and who in every respect conduct themselves as educated physicians and as gentlemen."

If these opinions of such recognized authorities are correct, and I do not doubt it, it is good evidence that, in the course of five or six decades, mutual observation and gradual deviation from our respective original standards have brought us and the homœopathists so near together that the similarities quite outnumber the dissimilarities.

Facts to be Considered by Obstetricians.

1. Since the last meeting of this Society, the operation of Symphyseotomy has been performed 18 times in the United States, and twice in Canada.

2. This operation was performed 11 times in Naples, and in no other locality, in 1891; but spread in 1892, from Italy to 8 other countries, and 71 women in all, were operated upon.

3. The Porro-Cæsarean operation has been performed 28 times in 13 years, in the United States, with 11 deaths; 7 died out of the first 10, and one out of the last 12.

4. The Conservative Cæsarean operation has been performed 75 times in the United States, with 28 deaths: 15 died of the first 25, and 3, of the last 25. Of the last 16, one woman died, and her child also. She was in labor seven days; had a placenta pravia, with a rigid os: she survived twelve hours, and her child two days.—*Robert P. Harris, M. D., to the American Gynecological Society.*

First Boy: "No, sir, you don't catch me shamming off sick to stay home from school and get dosed up with castor oil and such stuff." Second Boy: "Oh, I'm all right on that. We're homœpaths at our house."—*Life.*

SOCIETY REPORTS.

THE MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, March 17th, 1893.

THE PRESIDENT, Dr. F. C. Simpson, in the Chair.

CHRONIC ARTICULAR RHEUMATISM.

DR. A. M. VANCE: I have a little girl at the Children's Hospital that was sent in the other day by the Charity Organization the subject of chronic articular rheumatism. A curious feature of the case is that this growth was found on the large finger of the left hand. It is about 1½ inches in length and seemed to be a horny extension of the finger nail. I have seen the condition several times before.

CONGENITAL CLUBFOOT—OPERATION

No. 2. The other specimens are astragali removed from a case of congenital clubfoot, child two years old. I saw this patient when a month old, but did not begin treatment until it was three months old, owing to the very small size of the feet. I treated them with comparative regularity for some time, but was never able to correct the position of the feet without operation. It was an extreme case of equino-varus. The bones were removed by a semilunar incision on the outer side of the feet, and the result has been very satisfactory. It is the first time I have ever removed any of the tarsal bones for the relief of talipes, but I am certain a cure in this case could never have been accomplished without the bone operation. I am now able to get the feet in almost perfect position, and the ankle joints seem to be about as good as normal. Edidently the astragalus had nothing to do with the movement of the joint, as it was entirely outside of the arch.

DISCUSSION.

DR. C. W. KELLEY: I would like to ask Dr. Vance if there is a motion of the joint where the astragalus is removed; what the future of these cases is.

DR. W. L. RODMAN: In regard to the second case reported by Dr. Vance, removal of the astragalus: This is an operation that I believed was first popularized by Dr. T. G. Morton, of Philadelphia; my friend and class-mate, Dr. H. A. Wilson, who is Professor of Orthopedic Surgery of Jefferson College, is also fond of the operation. Before my last visit to Philadelphia he had performed the operation on both feet of a patient, and I saw the case about the second or third dressing. Whether or not there is perfect motion of the joint after this operation, it seems to me the question Prof. Kelly asks is a very natural one; what is the future of these limbs after the astragalus is removed? I am not sure whether good motion is secured after the operation or not.

DR. A, M. VANCE: I saw a number of cases operated upon by Morton, in which the feet were perfectly flat; the children, however, walked in a "peg-leg" style, had no spring, but were able to walk very well. By examining the foot you could get a good deal of passive motion, just as can be done in the case reported by me. I was opposed to his operation, and did not believe any infantile case would refuse to be relieved by the ordinary methods, but I treated this child under close observation for twelve months, using several mechanical appliances changing them three or four times. The feet were so very small, however, that no grasp could be gotten so as to make manual replacement sufficient to stretch the interior structures. There has been no trouble whatever since the operation; the wound healed perfectly; that is the right foot healed by absolutely primary union, the other had a discharge of synoveal fluid for a while, but no inflammatory reaction and is perfectly healed now. I have the feet in over-correction now in boots. A week ago I changed the boots and tested the motion, which seemed about as much as in the normal foot. I believe they will have to be held in correction for quite awhile, as the structures on the outer side of the ankle are, of course, very much too long.

DR. W. L. RODMAN: What do you

think of the method advocated by Phelps, where he cuts through everything down to the bone, in these extreme cases of club-feet.

Dr. A. M. Vance: I believe, except in very extreme cases, it is unnecessary to resort to any surgical procedure greater than tenotomy and replacement, and even in extreme cases that have been walking four, six, or ten years, with bursæ development and hypertrophy of the bone, I have been able to relieve in an incredibly short time. I think the Phelps operation is good in certain cases as the results are brought about quickly, but it seems an unnecessary amount of cutting and I believe that these structures will remain tender. He cuts down through everything, blood vessels, nerves, ligaments, etc., leaving the gap to granulate and heal under antiseptic dressing. He reports wonderful results, but I do not believe his operation has been generally adopted by orthopedic surgeons. I believe that this cicatrical tissue is not as good as if we leave all the structures there, and further we are liable to have an over-correction by this treatment, which is even worse than club-foot.

Dr. D. T. Smith: You have all heard of the case of the Valedictorian of the University class, Dr. R. W. Bolling, who was, a few weeks before the commencement, suddenly attacked with a peculiar disease winding up with blindness. The symptoms were so little typical of any particular disease that there has been very great uncertainty about the diagnosis. As far as I can gather they were about as follows: Young man in good health on last Tuesday two weeks ago; took an active part in a snow-balling contest at the University, and some hours afterward, while warm, ran to a fire somewhere in the city, returning about eight o'clock. I think probably about eleven o'clock he was seized with a severe rigor which lasted for some time; the next day he had some fever without pain except in the legs over the joints; aching in the small of his back; intense nausea and for forty-eight hours persistent vomiting but no headache. I do not know whether the vomiting was projectile or not. At the end of the second day there appeared a coarse eruption on his body, and about that time an iridochoroiditis set up with result of complete loss of vision. I do not know just how long the eruption lasted, but it disappeared, and the joints then began to swell and were tender as well as painful. He gained after that some in general strength; his eye trouble going on from bad to worse, if not already as bad as could be. A week after that time he was able to walk a couple of blocks and went out two or three times. It was then discovered that there were symptoms of heart failure, pulse being rapid, irregular and weak, and it was found best to continue in bed. This evening after three weeks, he is scarcely able to be out of bed; very little appetite, still emaciated, growing weaker. I think he is probably weaker than he has been at any time previous. Mind has been clear except that he had delirium at the beginning of the fever.

The question is, what is the diagnosis, what was the cause of the condition? The diagnosis has been provisional; no certain conclusion having been reached. If cerebro-spinal fever, which I rather think it was, the absence of headache at any time makes it an exceptional case. The chill and vomiting were typical of this trouble. In certain cases of cerebro-spinal fever the disease has been mistaken for rheumatism owing to the pain and swelling of the joints. Swelling of the joints subsided after the eruption disappeared; there is weakness and indications of blood degeneration as shown by the debility and the irritability of the heart, etc. No trouble about the kidneys as far as I can learn.

DISCUSSION.

Dr. J. M. Ray: This young man was taken sick on Tuesday; Dr. Cottell saw him first. At the time measles was quite prevalent among the students and the suggestion was that it was possibly a case of measles. Later the spots became much larger than the eruption of measles, and it was suggested that they resembled very much, varioloid. I was called to see the patient. I found him complaining very much about his eyes, intense fear of light and great conjunctival injection. He was in a darkened room so that it was impossible to make a thorough examination. I did not have my ophthalmoscope with me, but opened the window and tried to reflect a light upon the eye, but he was so intolerant to light that I did not succeed in

getting a close examination. The pupil failed to respond well to light. I did not make any diagnosis, but ordered atropia and hot applications. When I saw him again the anterior chamber and everything in front of the pupillary space was blocked with pus. Coming on so rapidly I knew that such an inflammation would probably be disastrous to sight and gave an unfaforable prognosis. The eruption still continued and there was on the arms and chest large, dark, diffuse spots similar to hemorrhagic measles. The eye symptoms went on without varying their course until the entire tract was involved in an extensive inflammatory condition, and infiltrated throughout with lymph and pus. I made an incision through the cornea letting out the pus, and washing out the anterior chamber as well as I could. The pus was so thick and so mixed with lymph that a quantity was pulled out with forceps and cut off. The eruption took a peculiar course; the second time I saw the case I noticed large purplish spots and about the same time the wrist and elbow joint became involved. The elbow swelled until it was much larger than normal, also the fingers and wrist joint became involved. On the chest and along the legs there were large elevations which were very red and tender on pressure. The toe joints also became inflamed and very tender. These subsided without evidence of pus formation. His mother says he had measles when a child. There was a child in the house about two years old that has never had measles and this child played around the room and has not developed measles. In conclusion I would say it is evident that the purulent condition in the eye is secondary to some constitutional trouble, but just what I am unable to say. I have seen similar conditions following cerebro-spinal meningitis.

Dr. C. W. Kelly: What was the pulse?

Dr. J. M. Ray: The temperature ran up to 103° F. I never noticed particularly as to the pulse (as several physicians saw the patient) until after the general symptoms improved and I was left in charge of the case, then I watched the pulse and noticed one day it went up to 120°, very irregular and weak. I asked him about it, and he said he had noticed his heart had been out of fix at times ever since he had been sick; on this particular occasion he said he thought he had used too much atropia in the eye producing this rapid and weak pulse.

Dr. S. G. Dabney: Rheumatism would be the first thought in my mind. The eye symptom developing in connection with inflammation of the joints, fever, heart disturbances, etc.—I have seen symptoms very similar to those following rheumatism. I think a number of us saw such cases about a year ago. I reported one case to this society at that time, occurring in a young lady. I believe rheumatism is often accompanied by an eruption of this character, and would like to ask the question if this is not the case.

Dr. J. M. Ray: The joints were not sufficiently reddened and sufficiently tender to suggest acute articular rheumatism. I understand there is no rheumatic history and purulent eye disease is not characteristic of any form of rheumatic trouble with which I am familiar. If it be rheumatism the eye disease is more likely to be simply plastic.

Dr. C. Skinner: In answer to Dr. Dabney's question in regard to rheumatism: I have seen several cases of rheumatic trouble attended with spots on the skin. Very frequently there is a great tenderness of the joint and occasionally intense pain, still no swelling or redness. I want to mention one case that I have seen within the last two weeks, which is just like the one reported except the eye symptoms. Dr. Rodman will remember I asked him to assist me in the enucleation of a tumor of the axillary space in a child which operation did not materialize. I was called to see its mother, a lady suffering from an attack of rheumatism; I saw her with pain in both wrists and both ankles. The second day after the first manifestation she called my attention to a number of spots over her arms; upon further examination I found these spots extended over the whole body especially on the legs and thighs, large red spots, tender and very sensitive. I made diagnosis of acute articular rheumatism, and put her on salicylate of soda in very heavy doses. The symptoms partially subsided but did not entirely leave her until I stopped the salicylate. I then gave her bicarbonate of potash; there was some nausea possibly due to the fact that she was taking so much medicine. For a day or two her temperature was 102°F. There was no photophobia or condition of the

eyes to attract marked attention; and no headache that I could attribute to the rheumatic trouble.

Dr. A. M. Vance: It seems to me the case referred to by Drs. Smith and Ray must have had some marked septic origin; (I believe this theory has not yet been mentioned) septic material introduced from without even through very small inlets might give rise to the symptoms present in a very short time. I feel sure that this must have been the cause of the trouble.

Dr. J. G. Cecil: I believe that the case referred to has something to do with quite a number of very obscure cases that I have heard of recently. I have seen three or four lately that while they were not in every respect similar to this case, in some respects they were. I was called by one of the students at the University to see a young lady who had come in town to attend the commencement exercises last week. On Tuesday she was seized with quite a violent attack of fever accompanied with intense nervousness and headache. When I saw her temperature was 104½ to 105° F., she had exquisite tenderness about the wrist joints and very slight redness. The case looked to me like one of acute rheumatism and I so expressed myself, put her upon a course of salicylate of soda after having given her a purg. The fever went down rapidly and never rose again; she went home today practically well without any further manifestation of the rheumatic symptoms. In the same house a student of the University was also afflicted at the same time with very nearly the same symptoms; intense headache, nausea, vomiting, high fever and delirium. I did not see this case but was told by Dr. Goodman about it. A week ago I was called to the country to attend the daughter of a physician well known to most of us, who was seized very suddenly with intense fever, 106° F. and delirium from the start, very much impressed and remained so for two or three days. I saw her on the third day of the illness, temperature then 105° F., she had some tenderness about the ileo-cæcal region. It was feared she was developing appendicitis, or there was some obstruction of the bowel, but this afterward proved not to be the case; the fever likewise went down gradually without any special attempts at reduction by medication, and she is about well now. So it seems to me there is a peculiar class of fevers—I do not know whether they should be called fevers or not—but of diseases that are prevalent at this season of the year, which I cannot understand. I do not know what they are. All of them thus far that have come under my observation have terminated favorably. Some of the cases have been diagnosticated one thing, and some another and I believe I have been disappointed in the diagnosis of every case. I have been forced to the conclusion that they are irregular or unusual forms of grippe. None of the cases referred to by me have shown any special eye symptoms.

Dr. D. T. Smith: I have seen three cases of a similar character to those reported by Dr. Cecil, within the last week, the initial symptoms in every case being intense pain, headache and fever. I have been a little backward about saying it, but I have not been able to classify them except by supposing that there is a mild form of cerebro-spinal fever prevalent in the city.

As to the case of the student Dr. Bolling: The vomiting and chill would not indicate rheumatism; this disease never commences with persistent rigor. Rheumatism never commences with persistent uncontrollable vomiting lasting forty-eight hours. I think cases of cerebro-spinal fever must have been mistaken for rheumatism on account of the joint involvement. Taking into consideration all the symptoms in the case reported by me, and those referred to by the several speakers, I am very strongly inclined to the opinion that the trouble is cerebro-spinal fever.

CASE OF APPENDICITIS—OPERATION—DEATH.

Dr. A. M. Vance: I was called by Dr. McDermott at three o'clock yesterday to see a gentleman; German; forty-nine years of age; very fleshy. He gave the history that in January he had some bowel trouble which yielded to castor oil and he recovered. In February he had another attack preceded by diarrhœa which was relieved. For a week prior to the time Dr. McDermott was consulted (he was called sixteen hours before he asked me to see the case) the man had been feeling a little "out of sorts," but he thought it

was an attack similar to those he had formerly suffered with and kept around attending to his business. At five o'clock Wednesday afternoon he was taken suddenly with great pain in the abdomen, and he got up stairs with difficulty and went to bed. Dr. Geo. F. Simpson was called in and gave the man a hypodermic of morphine, Dr. McDermott came several hours later and found the man with marked symptoms of shock; he made diagnosis then of probable appendicitis. It was necessary to administer more morphine on account of the severe nature of the pain, salines were given without result, pulse gradually increasing in frequency, temperature 103° F. at one time. I saw the patient at three o'clock yesterday, found temperature 101½° F. pulse 120, abdomen very much distended, great rigidity of the abdominal muscles, considerable tenderness over the whole area of the peritoneum, tenderness being particularly referred, however, to the McBurney spot. We advised an operation at once; Drs. Roberts, Kelly and Anderson afterward saw the case. Last night at seven o'clock the abdomen was opened; an incision was made between the anterior superior spinous process of the ilium and the umbilicus. The man was very fat, fully three inches of adipose tissue was encountered before the true wall was reached. As soon as the peritoneum was punctured pus came out in considerable quantities. With some little difficulty the appendix was found and removed. At time of the operation the man's pulse was 128. The appendix was quite small and as it was lifted out the distal end was torn and separated, but before it was torn Dr. Roberts and I detected a perforation about the size of a match in the lower portion. The two pieces of appendix have been carefully put together by Dr. Anderson and you can plainly see signs of great localized congestion and make out the perforation. The appendix between this congested end and the cæcum was very small and white. The man had general suppurative peritonitis, rupture having taken place probably at five o'clock day before yesterday afternoon when the severe symptoms developed.

This instance shows how treacherous these cases are and how important it is to make early diagnosis if possible, so that relief may be obtained by surgical procedure. I have operated twice recently where perforation of the appendix was about to take place, and the patients recovered; I have operated twice where perforation had already taken place and both patients died. This man died four hours after operation in shock. He secreted very little urine for several hours prior to operation, and two hours after the operation had been performed I catheterized the bladder and drew off about an ounce of urine; I examined it and found albumin.

DISCUSSION.

Dr. T. L. McDermott: Dr. Vance mentions two cases of appendicitis in which he operated before perforation took place and in which the operation was successful; also two cases in which perforation had taken place which were not successful. This is the point I want to call attention to. I have had in the past week two or three cases of colic in which there was evidence of as much distress as this patient had. I have frequently had cases of colic in which there were symptoms apparently just as severe as have been found in cases where appendicitis has been made out and where peritonitis has followed, and it has been a serious question in my mind whether often in cases where appendicitis has been diagnosticated they were not purely cases of colic. While this man had the general symptoms of appendicitis still, owing to his having had several similar attacks and owing to the peculiar condition of the patient, I did not feel that I was justified in saying so positively and advising operation. I do not believe if Dr. Vance had been present when I first saw the patient, he could have said positively that it was appendicitis. The question is whether it is wise to recommend an operation as serious as a laparotomy in cases that may prove to be nothing more than ordinary colic. I am sorry now, however, owing to the fatal outcome of the case, that Dr. Vance did not see the patient with me early in the attack; still as I had treated this patient in several similar attacks, I had no reason to believe that relief would not follow ordinary treatment as had been the case on previous occasions. How can we discriminate in these cases between ordinary colic and appendicitis when the symptoms are often identical. The responsibility is very great and certainly it would be a

mistake to go into the abdomen in ordinary colic. It is a serious question in my mind whether laparotomy is indicated in these cases. I do say frankly, however, that in the two cases upon which Dr. Vance operated, I believe the result would have been the same with or without operation. While I am a little chaotic in regard to these cases, I believe in another case I shall summon consultation earlier, but in the case reported I do not think operation would have been successful had it been performed earlier. The operation was performed twenty hours after the seizure, four of which were necessarily lost in the attending consultation and subsequent preparations.

Dr. Turner Anderson: In the case reported I do not see how it would have been possible to have made a diagnosis that would have justified a laparotomy earlier than was done, especially as the patient was able to be up and attend to his business only a few days prior to his death, and, further, as he had been subject to frequent attacks of abdominal trouble which yielded promptly to the ordinary treatment.

Dr. A. M. Vance: I do not believe it is ever possible to tell just exactly the condition we will encounter when the abdomen is opened, but I do think diagnosis can be made with sufficient accuracy to justify operation in nearly every case. Drs. Anderson and McDermott, in my opinion, have both laid too much stress upon the dangers of a laparatomy. It is now a well established fact that laparotomy in competent hands and under favorable surroundings is a comparatively safe surgical procedure, and the operation performed last night, had it not been for the patient's serious condition, could have done no possible harm. Therefore, I think in the not far distant future all of these cases will be operated upon in the stage that Dr. McDermott first saw this patient. I believe that these cases ought to have the benefit of the doubt and a laparotomy be done for the purpose of diagnosis; I believe that this will eventually be the practice.

In regard to the differential diagnosis—I would not be so presumptuous as to say positively in every case that I could tell exactly the conditions that would be encountered when the abdomen was opened, but I cannot think of anything else but perforative appendicitis or perforation of the bowel owing to some other cause that would produce general peritonitis in the male except traumatism. Of course the perforation of typhoid fever is not considered in this case, as there is no such history. Dr. McDermott made the diagnosis of appendicitis when he first saw the patient, and I firmly believe if operation had been performed then, the chances would have been very favorable for recovery.

Treatment of Hip Disease.

Townsend (*New York Med. Jour.*) considers this subject under the following heads:

1. General Treatment.—Improve the hygienic surroundings, out-of-door life, change of residence to the seaside or mountains, tonics and cod liver oil.

2. Local Protection to the Joint.—Two methods—rest in the recumbent position, and immobilization by the aid of a splint while the child goes about.

3. Treatment of Abscesses.—Free opening is preferred when abscess is large, followed by scraping and treatment by iodoform, guaiacol or balsam of Peru.

4. Correction of Deformity.—By (1) rest in bed with extension; (2) immobilization of the joint; (3) forcible correction without an anæsthetic; (4) correction under an anæsthetic. The first two methods are preferred.

5. Excision.—Except in rare cases, excision should be restored to only when abscesses are extensive, destruction of bone great, or the hip of the patient endangered by excessive suppuration or amyloid changes. Koeig's statement, that four-fifths of all patients with tubercular joint disease have also other forms of tubercular disease, is probably an over-estimate; but one of the principal arguments in favor of excision has been much weakened since it is now known that but rarely the bone lesion is the only focus. The author considers that excisions are seldom called for.

Alcoholism (Chronic).

Dr. Gerhard recommends the following:

℞ Tincturae capsici.....
Tincturae zingiberis āā..... ʒi.
Tincturae valerianae ammon....
Tinct. gentianae comp. āā. ..... ʒii.

M. Sig. Take a dessertspoonful in a teacup of hop tea three or four times a day.

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 = 18 = 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, MAY 27TH, 1893.

EDITORIAL.

A GRATUITOUS INSULT.

We recently received a circular letter from a medicine company offering "a splendid chance to make money, a chance of a life-time to secure a fine business—honorable, legitimate and large paying." A yellow folder contained information and encouragement to prospective agents and gave a list of premiums ranging from a five-shot revolver to a "gent's solid gold hunting-case watch." References were given to a number of business houses and individuals, including several whose names one would scarcely expect to find in such a list. Accompanying the folder was a copy of *The ——— Medical News and Literary Casket*. Passing over the literary gems, we are more interested in the announcement of Dr. So-and-so's Cascara Compound, his King of Pain ("for aches, pains and soreness of all kinds, external and internal, also wonderfully curative in cholera morbus, diarrhoea, dysentery and all looseness of the bowels"), his celebrated liver pills and several other proprietary compounds bearing the names of other "doctors." The last page of this periodical is filled with reports of wonderful cures by physicians, clergymen and others. One fond father writes "I had a child that got so bad with worms that they crawled out of its nose and mouth. I used a box of the worm confections which knocked them stiff and I have all reasons to believe, saved the child's life."

After the first feeling of amusement passed away, we confess to a growing resentment at the audacity of a company which requests physicians in good standing to act as peddlers of its nostrums and which boasts "We point with pleasure to the fact that among our agents are found many of the most successful physicians of the country." Yet we can hardly deny that this assertion has some foundation in fact, since we find frequent instances of regularly graduated physicians engaging in all sorts of quackery and since men of renown in the profession lend their influ-

ence to the use of secret compounds whose only plea of respectability is that they are not openly advertised to the laity. It goes without saying that shrewd business men will not waste printing and postage in scattering their advertisements among medical men unless they have good reason to believe that, in a profitable proportion of cases, a favorable response will be made to their overtures. The responsibility of this deplorable state of affairs rests not with the medical profession as a whole but with the men who grant diplomas and who admit uneducated, almost illiterate students to medical colleges. If a decent general education were a prerequisite to matriculation in every medical school and if a thorough acquaintance with strictly medical studies were required before graduation, there would be little trouble in drawing the line of demarcation between legitimate practice and nostrum-vending, without fear that the latter would encroach upon the former.

Professional dignity is not, however, the only sufferer from the patent medicine evil. The people who contribute so lavishly their praises of panaceas, and who allow themselves to be snatched from the grave with such facility, after having been given up by several prominent physicians, are the real victims. There are certain proprietary medicines which are in themselves good enough prescriptions; for example, several pleasant laxatives, an English gout remedy, and a brand of quinine pills without which, it is said, that southern Michigan could never have been settled. Even these nostrums, however, are good only when compared with their viler rivals. The first need of a sick person is good medical advice and diagnosis, and the second properly adapted medicines. We can scarcely imagine if a tailoring house should advertise clothes of the best quality expressed at reasonable rates to any one who should order them by measure, that many persons would feel confident of their ability to fit themselves. But in the case of quack medicines, not only do people show the blindest confidence in the quality of the preparations advertised, but with the most amazing facility they make diagnosis of kidney and liver trouble, consumption and malaria. Fortunately for their vanity if not for their health, the misfits between the measurements of the needs of their internal organs and the ready-made cure-alls are not so apparent as if they were worn on the back.

Another and more dangerous class of proprietary medicines is illustrated in the "King of Pain," for internal as well as external use, with which prospective medical agents are to perform deeds of philanthrophy while acquiring a fortune for themselves. We can look with some degree of equanimity on sarsaparillas and other tonic nostrums but we must remember that a medicine advertised to remove a definite and easily recognized symptom must contain a large dose of a powerful drug. Headache powders are likely to contain excessive amounts of acetanilide and cocaine, while the diarrhœa and pain medicines are, almost without exception, opiates.

In our opinion, the laity are themselves responsible for the existing state of quackery. Privately and publicly have they been warned against this evil. Individual avoidance and concerted prohibitory legislation lie entirely in their power but as long as they prefer to attribute arguments of the regular profession to selfish motives, quackery will continue to flourish. While, however, we may resign ourselves to the inevitability of the patent-medicine business, we, at least have the right to demand that it shall keep aloof from the regular profession without attempting to proselyte our weaker brethren.

TRANSLATIONS.

Contributions to the Pathology of Psoriasis.*

The author, Dr. J. Schutz, reports a hundred cases occurring in his private practice—66 male, 34 female. Ninety-five cases ranged between the years of 9 to 24. One had arrived at the age of 64. Three occurred in the second and one in the third year.

A history of heredity was present in 28 cases; in all cases without exception there was a profuse growth of hair, particularly on the outer side of the arms and shoulder blades. The color of the hair was black in 18, dark brown in 57, light blond in 25. The complications met with, were acne (6 times); lichen pilaris of the extensor surfaces of the extremities, (4 times); furunculus of the neck, (5 times). Eczema was never noticed. One patient suffered from diabetes, two from tuberculosis. The seat of eruption was not uniform as a rule; generally, however, the plantar and palmer surfaces, the upper eye-lids and mucous membranes are not attacked. The extension of the eruption is usually symmetrical; a return on a previously cured location presents greater difficulties for treatment.

The eruption seems to have a predilection on surfaces where the integument is stretched, or where the bones are immediately under the skin. The cranium was the seat of primary attack in 36 cases and in 11 cases it began primarily around the nails (Psoriasis of the matrix of the nail.) In a case in which there was a return two (2) consecutive times, acute articular rheumatism accompanied the last attack. This confined itself to the larger joints. One joint of the arm became partially anchylosed. Bourdillon reports similar cases.

In another case in which there were two (2) consecutive returns, bronchitis formed one complication and at the other time ischiatic pains were present.

Microscopical investigations of the patches showed a deep infiltration extending down to the papillæ, which on removal would bleed readily.

The redness of the attacked portions was not due so much to hyperæmia as to the atrophic changes which allowed the blood vessels to be nearer the surface. Another factor was the dimunition of keratohyalin.

The occasional presence of odema in the connective tissues was regarded as a passive engorgement. Prognosis was favorable in those cases which had not been previously treated or had had but few returns. Complicating eczemas resulting from irritating applications, usually prolonged the cure, and predisposed to return.

The author concluded from his observations that it was better to err on the side of too little treatment than too much. Duration of treatment extended over a period of 4 to 11 weeks and consisted in the use of tried remedies; arsenic, tar, chrysarobin, pyrogallic acid, which usually proved satisfactory.

The history of two cases particularly interesting from the fact that a change of climate to a higher altitude, always brought about a spontaneous cure, the disease having attacked the entire body.—*Arch. f. Dermatol. u. Syph.* xxiv, 1892.

Collection of Statistics on Anæsthesia*

During the current year fifty-eight reports have been made by Gurlt of Berlin. upon this subject, many of which were collected in foreign countries.

The total number of cases anæsthetized are 57,541, of these 11,464 nitrous oxide was used in dental practice of the University of Berlin, and will be excluded from the following statistics. During the two first years of the collection of statistics on this subject, the figures stood at 157,815, among this number there were fifty-three deaths, making in all about one death in 3,000 cases of anasthesia.

Viewed from the standpoint of different anasthetics in relation to their mortality, we have the following figures; 1:2899 in chloroform, 1:4118 in chloroform and ether, 1:4538 in bromide of ethyl, 1:199 in pental.

With the use of absolute pure ether in 14,506 anæsthesias there has been no death recorded. These results encourage further use and investigation of ether narcosis.

Küster of Marburg and Trendelenburg of Bonn, express themselves in favor of ether as an anæsthetic.—*Müch. Med. Woch.*

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

Exanthemata During the Puerperium.*

Among 144 obstetric cases by F. Ahlfield at Marburger Clinic between December, 1880 to April 1892, the author observed 14 cases of rash resembling scarlet fever or measles occurring during the puerperium. In one case it attacked a patient who had undergone abdominal section. The rash was present in two (2) cases on the 2nd, 3d and 4th day after delivery; once on the 5th, 6th, 7th and the 8th day. It appeared twice as late as the 10th day and once on the 15th day.

The time of eruption and fever corresponded to the usual appearance of puerperal affections. In several cases other puerperal symptoms were noticed immediately after the appearance of the rash. The author, however, regarded it more as a complication than a sequence.

He concludes that these questionable cases, have nothing, or little, to do with scarlet fever or measles proper, and is reinforced in this belief by Mannkopff, who failed to trace it back to any source of infection, and further that no others were attacked by the same disease.

The author concludes then to place these under the head of septic exanthemata, believing that it is due to a peculiar poisonous product, and asks the question, why should not, among the numerous micro organisms which are found in the lochia, certain ptomains be present, which would have peculiar property of producing these exanthema?—*Ztschr. f. Gebutsh. u. Gynal.* xxv, 1-92.

ABSTRACTS.

A PRELIMINARY COMMUNICATION CONCERNING THE ANTISEPTIC VALUE OF PHENOCOLL HYDROCHLORIDE.

Carl Beck, in the *New York Medical Journal* April 22, 1893, writes: Bearing in mind the derivation of the well-known drugs—acetanilide, phenacetine, and phenocoll—it ought to appear natural, from a theoretical standpoint, that these descendants of a typical antiseptic should have preserved their characteristic germicidal qualities. Led by this consideration, I determined last summer to examine these drugs in reference to their antiseptic value from a practical standpoint by applying them on all kinds of wounds and ulcers in the shape of powders, solutions, ointments and gauzes in private practice, as well as at St. Mark's Hospital and the German Poliklinik, with the assistance of Dr. Stiebeling, Dr. Heyman and Dr. Handel.

My experiments have shown that all the drugs mentioned above possess a well-marked antiseptic power.

Acetanilide keeps a fresh, clean, or well granulating wound in a good condition, but is of little influence upon infected wounds or upon ulcers. It does not seem to produce irritation or eczema, and may rank the same as boric acid. (Experience of seven cases.)

Phenacetine is undoubtedly more powerful, and not only keeps fresh or well granulating wounds in a good state, but improves their appearance. A ten per cent. gauze did not have any odor three days after it had been taken away from an ulcer of the leg. Poisonous effects, irritation or eczema were never noticed. So far as its antiseptic value is concerned, it appears to me that it takes its place between boric acid and iodol. (Experience of thirteen cases.)

But I soon found that phenocoll far surpassed both, wherefore, for the last three months, I have experimented with this only, in the form of—

1. Pure powder.
2. Five per cent. watery solution.
3. Ten and fifteen per cent. Alcoholic solution.
4. Ten and twenty per cent. gauze.
5. Ten and twenty per cent. ointment (vaseline and anolin).

Originally I only used the powder by dusting it over the wound surface and covering the same with sterilized gauze or moss. It was employed in lacerated

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

wounds (five cases), suppurating glands of the neck (three cases), bubo inguinalis (two cases), badly granulating ulcers of the leg (two cases), suppurative mastitis (one case), amputation of three toes (one case), burn of the second degree, embracing the dorsal surface of the foot and anterior part of the leg (one case).

All these sores had been granulating well, and, with the exception of one amputation case, are cured to-day.

No irritation of the integument or any general symptoms which could be referred to the action of the drug were observed. When I found that I could do just as well with the ten per cent. gauze, I dropped the powder and for the last two months, with few exceptions, have used the gauze only.

The same good effects were obtained by covering the granulating surfaces with a thin layer of the gauze, which was protected, as a rule, by a piece of sterilized moss. The dressings were usually changed every third day, as the secretion was scanty. The cases thus treated were:

Lacerated wounds caused by knives, pieces of glass, splinters of wood, or other injury (fourteen cases); extirpation of tubercular glands of the neck (packing the cavity with the gauze—eight cases); furuncle of the neck (crucial incision—two cases); caries sterni (chiselling and packing—one case); suppurative mastitis (broad incisions and packing—five cases); partial resection of a tubercular elbow joint (packing—one case); panaritium (eleven cases); amputation of the finger (gangrene after bathing in pure carbolic acid —open treatment and packing); bubo inguinalis (extirpation of glands—four cases); resection of tubercular hip joint (partial union, cavity packed—three cases); total resection of tubercular ankle joint (two cases); resection of astragalus for extreme equino-varus (failure of union by first intention, open treatment thereafter); amputation of the big toe for caries (open treatment); amputation of three toes for caries (previously treated with powder); phlegmon of different parts of the body (free incision, scraping and packing—seventeen cases); ulcers of the leg; necrosed surface scraped first, then a thin layer of phenocoll gauze and tight dressing applied over it—three cases).

All these cases are either cured at the present time or are in an entirely satisfactory condition, The healing process does not differ from that observed during the use of iodoform. Every patient's urine was examined repeatedly without anything abnormal being detected, and no irritation took place. Two cases—viz., one amputation of three toes and one phlegmon of hand, mentioned above—had formerly been treated by iodoform and had extensive eczema, while phenocoll did not irritate at all.

The five per cent. watery solution was successfully applied as a wet application in one case of dermatitis and in one case of erysipelas(arising from a lacerated wound on the anterior part of the leg). The same solution was used with apparent success in three cases of recent gonorrhœa and four cases of leucorrhœa.

The ten per cent. alcoholic solution was injected into the joints in two cases of coxitis and three cases of tubercular (?) inflammation of the ankle joint, without any irritation. So far as the final result is concerned I am still in doubt.

The same injection was made into a carcinoma mammæ (relapse in and around the scar after amputation a year ago), and it has undoubtedly produced a decrease of size and painfulness in the cancerous tissue, so that further investigations seem certainly indicated.

The injection of a watery, and especially of an alcoholic solution was always followed by a slight burning sensation, which never lasted longer than about a minute.

The twenty per cent. ointment (preferably made with lanolin) was used in one case of ulcer of the leg and two cases of burns of the second degree. The granulations were of a good character, but the healing process seemed to take longer than it did under the use of the gauze.

So far it seems to be evident, from my experiments, that phenocoll hydrochloride is probably as valuable an antiseptic as iodoform, and stronger than dermatol, aristol, iodol, pyoctanin, europhen, etc.

Furthermore, it probably surpasses iodoform because: 1, it is odorless; 2, it dissolves easily; 3, it does not produce eczema; 4, it is not contraindicated in kidney disease; 5, on account of its non-poisonous effects it can be applied to very extended surfaces.

As a very small amount of the drug fulfills its purpose, the expense is small.

THE LIBRARY TABLE.

Diseases of the Skin, by Charles C. Ransom, M. D., Assistant Dermatologist, Vanderbilt Clinic, New York. The students' Quiz Series; Philadelphia: Lea Bros. & Co., $1.00

This volume, like the others of the series, is arranged in the form of question and answer. Several wood cuts illustrate, as well as uncolored illustrations can, the prominent features of some of the rarer forms of skin eruption. An appendix gives many useful formulæ for the treatment of skin affections. The volume is fully up to the excellent standard of those which have preceded it and very well fulfills the purpose for which it is intended—a remembrancer for the student and busy general practitioner.

Medical Pocket-Atlases—Obstetrics. Part I, Labor; by O. Schæffer, M. D., Assistant at the University Frauln-klinik in Munich. Translated and published under the supervision of J. Clifton Edgar, M. D., Adjunct-professor of Obstetrics in the University of the City of New York, etc. New York: L. Hydel.

By means of a series of 98 colored plates, the student is conducted through the different stages of labor; the positions of the fœtus in the various presentations, normal and abnormal, shown, and the steps of the operations of turning and the application of the forceps clearly pointed out. The explanatory text is concise and plain and the book puts a series of plates into the student's hand that cannot fail to be of great service to him and the moderate cost of which serves to enhance its value. The volume is of such a size as to be readily carried in the pocket. Other similar atlases on the subjects of pregnancy and gynecology are in preparation. The imparting of knowledge by means of pictures may be a reversion to primitive methods, but the information thus gained is likely to take a deeper hold on the student's mind and makes a more lasting impression than many pages of dry description. The authors and the publisher are to be congratulated on their work and we look with interest for the other volume of the series.

BOOK REVIEWS.

Handbook of Hygiene and Sanitary Science, by George Wilson, M. A., M. D., F. R. S. Edin.; pp. 751. Philadelphia: P. Blakiston, Son & Co., 1892. Price $3.25.

This is an instructive work, notwithstanding its localism, applicable more to Great Britain than to America, and its attempt to technique without sufficient data to aid the general practitioner of medicine and at the same time falling short of being in the least instructive to the specialist. For instance on page 240, section III., Microscopical and Biological Examination in Water Analysis, he says: "A ready method is to take a measured quantity of the water, say .5 or 1 c. c., mix this in a test-tube with nutrient gelatine, and pour over a glass plate, which should be placed under a bell-jar with suitable precautions to exclude the entrance of atmospheric impurities. After a few days the micro-organisms or spores develop into colonies which may be differentiated as bacteri, moulds, fungi, etc., while subcultures of these colonies may be made if deemed desirable."

Owing to the rapid strides in this branch of science and the growing appreciation by the medical profession of the necessity of higher education in Preventive medicine a new edition of Wilson's Manual of Hygiene has long been demanded. The work is broad and comprehensive, on the etiology of the disease, particularly in relation to the germ theory on the functions and constituents of food stuffs, dietaries, diseases which render the flesh of animals unfit for food, air and its impurities, impure water and its effects on public health making it together with its interesting biblography one of the most valuable Handbooks of Hygiene and Sanitary Science for the general practitioner of the present day.

A Pharmacopœia for Diseases of the Skin, by James Startin. Third Edition. London: H. K. Lewis, 136 Gower Street, W. C., 1892.

This little book contains a concise formulæ; baths; rules of diet; classification and therapeutical index; giving various medicines and drugs commonly used in the treatment of skin eruptions. That this little book should have reached its third edition is ample proof of its appreciation not only by the student but the medical practitioner as well. It will be found of greatest assistance to Medical Practitioners engaged in active practice; as diseases of the skin, more than any other human maladies, are under the patients' observation, so as to enable him to detect an error and judge of his own progress, and perhaps no branch of medical education is more appreciated by the sufferer or more useful to the medical practitioner.

CURRENT LITERATURE REVIEWED.

THE MONTREAL MEDICAL JOURNAL

For May contains a discussion on tuberculosis in its various relations.

D. McEachran, F. R. C. S., V. S. Edin., D. V. S., contributes a paper on

The Inter-communicability of Tuberculosis from Animals to Man and from Man to Animals.

After reviewing the work of the various investigators of the subject, the author comes to the following conclusions: (*a*) Tuberculo-

sis is an infectious, fatal and incurable disease. (*b*) It is communicable from man to animals, and has been communicated by inoculation, by ingestion and by inhalation in the dried form of the sputum of consumptive persons, as well as from the tubercular matter itself, to cattle and to man himself. (*c*) Tuberculosis in man is identical with tuberculosis in the bovine and other domestic animals, is due to a slender rod-shaped bacillus, which gaining entrance to the circulation by means of milk, flesh, sputum moist or dry, work their destructive operations in various tissues of the body, not in the lungs only, as is often supposed, but in the serous membranes, pleura, peritoneum, thoracic and abdominal glands, or superficial glands of the body, especially the udder, testicles, thyroid, parotid and other glands, and not unfrequently in the subcutaneous tissues in various parts of the body, in the meninges of the brain and spinal cord, and in the human subject, frequently in the intestinal tract, and in many cases in animals it affects the articulations.

The author knows of no country where cattle are domesticated in which tuberculosis does not exist. Statistics go clearly to show that it is on the increase. The manner of the spread of the disease among cattle is as follows: A tuberculous animal, bull or cow, is introduced to the herd, the bacillæ are coughed up, provided the lungs be the seat of the tubercular formations. The sputum may mix with the food in the trough in front of the adjoining animal and thus be swallowed; it may dry on the hay, feed-box or boards to be inhaled; in the former case it may develop messenteric tuberculosis, in the latter pneumonic or thoracic. It may be, if a cow, that other calves besides her own are fed on her milk, which containing the tubercular bacillæ, they become infected. If a bull, he may in the act of coition transfer the bacilli to the cow. No more frequent source of extensive spreading of the disease exists than tuberculous bulls. The calf is sometimes born tuberculous. He has seen cases where the placental membranes were studded with grape-like tubercles.

It is generally said to be hereditary—it is, but more frequently the calf contracts the disease from its tuberculous mother's milk or coughed up bacillæ. It is generally supposed that the milk will not communicate the disease to the calf if the udder is not tuberculous. This is an erroneous and a dangerous doctrine, and in connection with the communication of the disease by means of milk to mankind should be strongly rejected.

The author looks for much good to result from the use of tuberculin as an aid to diagnosis in doubtful cases. The manner in which the disease extends to man through milk also receives careful attention from the author. He especially warns the profession against the commonly received doctrine that milk is free from harm unless the udder be tuberculous.

Dr. J. G. Adami discusses the subject of

The Communicability of Tuberculosis from Man to Man,

quoting the results of various researches in this direction. Especially striking are those of Cornet among the sisterhoods in Germany to whose lot the nursing of the sick in the hospitals falls.

Taking thirty-eight of these nursing corporations he found that, during the last 25 years, of their total mortality 62.8 per cent., or almost two-thirds, was recorded as being from tuberculosis, while of those members of the corporations dying between the ages of twenty-five and thirty-five no less than 73 per cent. had succumbed to this disease, in place of a little over 40 per cent. in the general population. Or, to put the matter in another light, a German nurse, member of one of these sisterhoods, *has at twenty-five the same expectation of life as a woman at fifty-eight in the general population.*

If, as Ransome has proved, the breath of a phthisical patient contains the bacilli, *a fortiori* are the bacilli present in large quantities in the sputum, and it is this sputum that must be rigorously disinfected. Not only must this be collected in special utensils and then disinfected and the utensils rendered sterile by boiling daily (or, as some advise, be made of such materials that they can only be employed one day and then be cast into the fire), but the handkerchiefs and bed linen must be washed apart and well disinfected, the habit of promiscuous expectoration must be stopped sternly, and when a patient has died or has left a room then the walls and floor of that room must undergo thorough disinfection.

All these precautions are absolutely necessary, and it is our duty to publish them widely abroad, if the spread of tuberculosis is to be averted. The fact so often noticed of the husband of a tubercular wife contracting the disease is also quoted by the author in support of his opinions. The fact of intestinal tuberculosis occurring most frequently in the young whose principal article of food is milk is spoken of as showing the infectious nature of the milk from diseased cows.

The milk he believes to be more infectious than the flesh.

Dr. William S. Morrow contributes a paper on

Masked Tuberculosis,

reporting cases in which the insidious nature of the disease was clearly marked. Koch's lymph, he thinks, may yet have a recognized place in the diagnosis if not in the treatment of tuberculosis. As an aid to diagnosis he regards as of great value the cherry red color given by Ehrlich's diazzo solution with certain specimens of urine. He has found this reaction in the urine of miliary tuberculosis, pulmonary phthisis, tubercular cystitis and tubercular peritonitis. It is usually present where absorption of tuberculous products is going on to any extent; and although the diseases in which it may be found are not yet completely worked out, there are certainly not many in which it is so typical as in tuberculosis and typhoid; and he believes we may often get valuable information by the employment of the test in these diseases.

Dr. F. H. Wetmore reports a "Case of Acute Circumscribed Hemiglossitis, with Suppuration." This number concludes with

the address to the Graduates of McGill University delivered by Dr. A. D. Blackader.

THE ANNALS OF GYNECOLOGY AND PÆDIATRY

For May contains a paper by Dr. Howard A. Kelly entitled

My Recent Ureteral Work.

After dwelling on the close relation between disease of the ureters and other pelvic conditions with which the gynecologist has to deal, the author minutely describes the anatomical relations of the structures under consideration and then proceeds to the subject of palpation of the ureters. In regard to this he says: "The ureter can be palpated through the anterior vaginal wall from its terminus in the bladder up to the point where it passes beneath the broad ligament. It is rolled in the loose cellular tissue under the index finger, or often better bi-manually under two fingers, or in advanced pregnancy on the head of the child like a narrow tape or flattened cord, without hardness. It must not be mistaken in this position for the obturator artery or nerve, or the upper border of the levator ani, or fibres of the obturator muscle, or the rim of the foramen. A diseased ureter becomes nodular and thickened, and is peculiarly prone to be mistaken for a cellulitis or an adherent ovary." The author states that many cases treated for cystitis or irritable bladder are in reality suffering from disease of the ureters. An enlarged ureter can also be palpated per rectum behind the broad ligament, and followed up over the posterior pelvic wall. He has also found that "the normal ureter can be traced and minutely examined in the upper part of the pelvic course by introducing a ureteral catheter through the urethra and bladder into the ureter, and carrying it up to or over the brim of the pelvis." His landmark for the upper portion of the pelvic ureter is the internal iliac artery, which can easily be felt per rectum. He does not know of any satisfactory means of locating the abdominal portion of the ureters by surface landmarks. His own method is to "locate the promontory of the sacrum by pressure through the abdominal wall, and from this to locate the point at which the ureter enters the pelvis from three to three and a-half cm., outside of and a little below the promontory; by pressing deeply at this point, the fingers at once recognize pulsations of the common iliac artery, a sign that the correct spot has been found. A large ureter can be felt at this point through thin walls. The patient will always complain of a severe pain, and often a desire to urinate when a sensitive or inflamed ureter is touched." The advantages of catheterization, sounding and dilating the ureters is next dwelt upon, the author reporting several cases of carcinoma, hæmaturia, hydro-ureter, stricture of the ureter, pyelonephrosis, and enlarged spleen mistaken for kidney in which the above procedure was of use. He observes the following routine in catheterizing: "First all the urine in the bladder is drawn off and put to one side, then the bladder is distended with a methyl-blue solution. It is now evident that if the catheter enters the ureter in the catheterization and clear urine is discharged by the catheter it does not come from the bladder. There is one possible source of error—when the lower part of the ureter is so distended that the water from the bladder backs up into it and so escapes through the catheter; this will be obviated by carrying the catheter still higher up." "The usual method of using the catheter is the one followed by Pawlik, by retracting the posterior vaginal wall and introducing the ureteral catheter into the bladder, and turning its point forward and trying to introduce it by observing the play of the point of the catheter over the anterior wall, as it seeks the ureteral folds. The ureters lie a little above or to the upper part of this fold, one or two centimetres to the right and left of the median line." To estimate the amount of urine from each kidney the catheter is left in position for a definite number of minutes and all the urine passing is caught in a minim glass. From this quantity, added to the amount retained in the catheter, the total amount for twenty-four hours can be readily calculated. The article is illustrated by half tone pictures and wood cuts of the anatomy of the parts and the instruments used.

Dr. Gebhard contributes a "Report on the Progress of Gynecology and Obstetrics in Germany." The paper includes a description of the operation of symphysiotomy and the recent bacteriological observations on the gonococcus in its casual relation to pelvic inflammations.

Dr. J. M. Baldy contributes a paper on "Complications Following Abdominal Section," reporting two cases that died of pneumonia immediately following the section. Another patient had uremia but recovered.

Dr. Carl Crisand discusses the subject of

Dilatation of the Cervix Uteri for Dysmenorrhœa and Sterility,

and quotes the opinions of gynecologists for and against the operation. He thinks that, while the operation has been much abused, it should take its place among the various methods of treating dysmenorrhœa and sterility. The cases should be carefully selected. Unless there is a flexion of the uterus, or a small cervical canal the procedure is useless. Although he prefers rapid dilatation under ether, he had had good results from gradual dilatation once or twice a week for three or four weeks; waiting for the patient to pass the menstrual period and then going on till the next period. The operation should be performed under the strictest antiseptic precautions and it is equally imperative that the patient have perfect rest in bed, and one menstrual period passed through while in bed. We should make sure of the sufficient dilatation of the internal os, even to the extent of rupturing some of the fibres which run around this section of the uterus in a circular manner. The wearing of a glass stem pessary for several months afterwards is also advised.

Dr. S. M. Hogan reports a "Fibroid Tu

mor of the Uterus; Rupture about the Fourth Month; Operation; Post-mortem; Specimen;" which has already been given in THE MEDICAL AND SURGICAL REPORTER for December 3rd, 1892, page 889, in the report of the proceedings of the Southern Surgical and Gynecological Association.

Dr. H. B. Stedman reports a case of "Atresia of the Cervix Uteri following Electrolysis." A sound was pushed through the exudate under antiseptic precautions and the retained secretions liberated. The patient recovered.

In the Department of Pædiatry, Dr. Henry W. Stelwagon contributes a paper on

Molluscum Contagiosum; Impetigo Contagiosa; Ichthyosis,

being the notes from ten years' service (4,131 cases) at the Philadelphia Dispensary for Skin Diseases. In regard to molluscum contagiosum he says, "many of the cases, in fact almost all, tended after a time to spontaneous recovery. In many a mild mercurial ointment, white precipitate ointment usually, vigorously rubbed in, was used; lesions in which there was a tendency to pedunculation were either snipped off or a ligature thrown around them; and in a few obstinate and large sized lesions a puncture, followed by a light cauterization with the stick of silver nitrate, or with carbolic acid applied by means of a pointed stick, was made. In ichthyosis, "the treatment which gave the greatest alleviation consisted of daily or triweekly plain warm or alkaline baths according to the severity of the case, with the supplimental use of a salicylated ointment, 2 to 5 per cent. strength. In two or three of the more severe cases a small quantity of precipitated sulphur, ten to thirty grains to the ounce, was added to the ointment. The most satisfactory ointment base was that made up of equal parts of lanoline, vaselin and lard." As to impetigo contagiosa, "although the disease usually ran an acute course of one or two weeks, disappearing spontaneously, making it difficult to measure the effect of medication, yet it may be stated that treatment had a positive influence. That which gave satisfactory results was either an ointment of white precipitate, ten to twenty grains to the ounce, or a similar ointment containing five to ten grains each of the white and red precipitate to the ounce; it was well rubbed into the lesions, the crusts, if possible, having been first removed with washings of warm water and soap. In cases markedly itchy, and in which, therefore, excoriations were produced, and the disease kept up by autoinoculation, in addition to the above application to the lesions themselves, a lotion of boric acid, with one-half to one and a-half drachms of carbolic acid to the pint, was applied to the parts generally.

PERISCOPE.

NEWS AND MISCELLANY.

National Association of Railway Surgeons—The Annual Meeting.

Following is the programme for the sixth annual meeting of the National Association of Railway Surgeons to be held at Omaha, Neb., commencing Wednesday, May 31, closing Friday, June 2, 1893:

Wednesday, May 31, 10 a.m.

Call to order by the chairman of the committee of arrangements.

Address of welcome; by John M. Thurston, Esq., general solicitor Union Pacific railroad, Omaha, Neb.

Response to the address of welcome; by Dr. George Chaffee, secretary New York Association Railway Surgeons, Brooklyn, N.Y.

Introduction of the president; by Dr. W. J. Galbraith, chief surgeon Union Pacific railroad, Omaha, Neb., chairman of the committee of arrangements.

Appointment of the committee on nominations by the president.

First report of the executive committee.

A report of a case of contusion of the back and abdomen, followed in five months with intestinal lesions; by Paul F. Eve, M.D., surgeon L. & N. R. R., Nashville, Tenn.

Discussion opened by Dr. George J. Northrop, chief surgeon, D. S. S. & A., Marquette, Mich.

Report of a case of fracture of the astragalus; by Robert Burns, surgeon Concord & Montreal, Craigie Burn Wood, Plymouth, N. H.

Discussion opened by Dr. S. L. McCurdy, surgeon P. C. C. & St. L. R. R., Dennison, Ohio.

Wednesday, May 31, 2 p. m.

Call to order. Reading of the minutes of the morning session.

Report of committee of arrangements.

Report of secretary.

PAPERS AND THEIR DISCUSSIONS--SPECIAL PROGRAMME

Injuries of the cord and its envelopes without fracture of the spine.

1. History; by Dr. George Ross, chief surgeon R. & D. R. R., Richmond, Va.

Discussion opened by Dr. J. H. Murphy, chief surgeon C. St. P. M. & O. R. R., St. Paul, Minn.

2. Anatomical landmarks; Dr. Jabez N. Jackson, surgeon Wabash R. R., Kansas City, Mo.

Discussion opened by Dr. J. B. Murdock, chief surgeon P. C. & St. L. R. R., Pittsburgh, Pa.

3. Physiology of the spinal cord; by Dr. A. P. Grinnell, chief surgeon Central Vermont R. R., Burlington-Vt.

Discussion opened by Dr. J. C. Hearne, surgeon S. C. R. R., San Diego, Cal.

Wednesday, May 31, 8 p. m.

SPECIAL PROGRAMME CONTINUED.

Injuries of the cord and its envelopes without fracture of the spine.

5. Experimental research; by Thomas H. Manley, surgeon Central Park E. & W. R. R., New York, N. Y.

Discussion opened by Dr. B. Merrill Rickets, chief surgeon C. P. & V. R. R., Cincinnati, Ohio.

5. An experimental study of spinal myletis and meningitis; by Dr. George A. Baxter, division surgeon Chattanooga Southern R R., Chattanooga, Tenn.

Discussion opened by Dr. Solon Marks, chief surgeon C. M. & St. P. R. R., Milwaukee, Wis.

Thursday, June 1, 9 a. m.

Call to order.

Reading of the minutes of last session.

Report of the committee of arrangements.

Report of treasurer.

Report of nominating committee.

Election of officers.

PAPERS AND THEIR DISCUSSIONS.

President's address; by Dr. C. W. P. Brock, chief surgeon C. & O. R. R., Richmond, Va.

The relation of the railroad surgeon to public and international hygiene; by Dr. R. W. Bruce Smith, surgeon G. T. R. R., Seaforth, Can.

Discussion opened by Dr. G. P. Conn, chief surgeon C. & M. R. R., Concord, N. H.

The National Association of Railway Surgeons—Not a trade union but a philanthropic and scientific organization; by Dr. E. R. Lewis, surgeon Wabash R. R., Kansas City, Mo.

Discussion opened by Dr. Wm. H. Elliot, chief surgeon Cent. R. R. of Georgia, Savannah, Ga.

Thursday, June 1, 2 p.m.

SPECIAL PROGRAMME CONTINUED.

Injuries of the cord and its envelopes without fracture of the spine.

6. The clinical aspect of spinal localization; by Dr. Nicholas Senn, surgeon C. St. P. & K. C. R. R., Chicago, Ill.

Discussion opened by Dr. E. G. Cochran, surgeon M. C. R. R., Topo Chico, Hot Springs, Mex.

7. Diagnosis from the standpoint of the neurologist: by Dr. C. H. Hughes, consulting surgeon Mo. Pac. R. R., St. Louis, Mo.

Discussion opened by Dr. A. I. Bouffleur, surgeon C. M. & St. P. R. R., Chicago, Ill.

8. Pathology and pathological anatomy; by Dr. Samuel C. Benedict, surgeon R. & D. R. R. Athens, Ga.

Discussion opened by Dr. J. B. Murphy, surgeon N. P. & W. C. R., Chicago, Ill.

Thursday, June 1, 8 p.m.

SPECIAL PROGRAMME CONTINUED.

Injuries of the cord and its envelopes without fracture of the spine.

9. Prognosis; by Dr. Alexander J. Mullin, division surgeon M. C. R. R., Michigan City, Ind.

Discussion opened by Dr. C. M. Daniel, surgeon N. Y. L. E. & W. R. R., Buffalo, N. Y.

10. Treatment; by Dr. W. B. Outten, chief surgeon Missouri Pacific R. R., St. Louis, Mo.

Discussion opened by Dr. W. R. Nugent, chief surgeon I. C. R. R., Oskaloosa, Iowa.

Friday, June 2, 9 a.m.

Call to order; Reading of the minutes of the previous session.

Report of the committee of arrangements.

Report of the committee on publication.

Second report of the executive committee.

Election of honorary members.

Miscellaneous business.

Amendments to the constitution.

PAPERS AND THEIR DISCUSSIONS.

A case of injury to the bladder and rectum; by Dr. D. S. Fairchild, division surgeon C. & N. W. R. R, Ames Iowa.

Discussion opened by D. A. H. Middelkamp, surgeon Wabash Western, Warrenton, Mo.

The grave importance of too early special treatment in most eye injuries; by Joseph A. White, A. M., M. D., ophthalmic surgeon of the C. & O. R. R., Richmond, Va.

Discussion opened by Dr. Adolph Alt, consulting oculist, Missouri Pacific R. R., St. Louis, Mo.

The responsibility of the surgeon in suits for damages, against railway companies; by Dr. C. M. Woodward, surgeon C. J. & M. R. R, Tecumseh, Mich.

Discussion opened by Dr. J. W. O'Connor, chief surgeon, D. & R. G. R. R., Denver, Colo.

Friday, June 2, 2 p.m.

SPECIAL PROGRAMME CONTINUED.

Injuries of the cord and its envelopes without fracture of the spine.

11. Medico-legal aspects; by judge J. H. Collins, chief counsel B. & O. R. R. west of the Ohio River, Columbus, Ohio.

Discussion opened by Mr. Clark Bell, editor Medico-Legal Journal and secretary of the International Medico-Legal congress, New York.

12. Statistics of the amount of money paid by the railways of the United States during the last ten years for alleged injuries of the spine; by Dr. F. K. Ainsworth, surgeon S. P. Rd, Los Angeles, Cal.

Discussion opened by Dr. Harvey Reed, surgeon B. & O. Rd, Mansfield, Ohio.

13. Clinical report.

1. From a medical aspect; (a) permanent injuries; (b) alleged injuries.

2. From a legal aspect; (a) settled with suit; (b) settled without suit; (c) miscellaneous; by Dr. George Chaffee, surgeon Long Island Rd, Brooklyn, N. Y.

Discussion opened by Hon. William E. Jones, general claim agent Mo. Pac. Rd, St. Louis, Mo.

General announcements regarding the excursions, with directions, etc., by the chairman of the committee of arrangements.

ARMY AND NAVY.

U. S. ARMY FROM MAY 14, 1893, TO MAY 20, 1893.

Promotion.—Medical Department.—Major Johnson V. D. Middleton, Surgeon, to be deputy Surgeon General with the rank of Lieutenant Colonel, May 8, 1893.

Casualty.—Lieutenant Colonel Ely McClellan, Deputy Surgeon General, died May 8, 1893, at Chicago, Illinois.

Appointments.—Medical Department.—To be Assistant Surgeons with the rank of 1st Lieutenant, May 12, 1892: Alexander N. Stark, of Virginia; Charles Lynch, of New York; John S. Kulp, of Pennsylvania; Edward L. Munson, of Connecticut; Charles E. B. Flagg, of South Carolina; James M. Kennedy, of South Carolina, Guy C. M. Godfrey, of Ohio; William F. Lewis, of North Carolina.

The leave of absence on Surgeons certificate of disability granted Captain William G. Spencer, Assistant Surgeon, U. S. Army, is extended four months on account of disability.

Captain James C. Worthington, Assistant Surgeon, ordered to report in person to Colonel Chas. T. Alexander, Assistant Surgeon Genl., president of the examining board, appointed to meet at New York City, N. Y., at such time as he may be required by the board for examination as to his fitness for promotion.

Leave of absence for one month on Surgeon's certificate of disability, is granted Major Samuel M. Horton, Surgeon, San Diego Barracks, Cal.

The World's Fair.

FINAL ARRANGEMENTS FOR THE SALE OF TICKETS VIA THE B. & O. R. R.

For the benefit of those desiring to attend the World's Fair the Baltimore & Ohio Railroad will sell Excursion tickets to Chicago and return, at all stations on its line, at low rates. Tickets will be on sale until November 1st, and will be valid for return journey until November 15th, 1893. They provide for a reduction of 20 per cent. below regular rates. These ticket will be valid only for continuous journey. Tickets at higher rates will be sold that will permit holders to stop over at Baltimore, Washington, or any other point, going and returning.

Besides the opportunity of visiting Washington, a privilege afforded by no other route, tourists via the Baltimore & Ohio Railroad will traverse the historic Potomac Valley, the theatre of the war between the States. At Cumberland they will be offered a choice of routes, via Pittsburgh, or across the Allegheny mountains, 3,000 feet above the level of the sea and via Deer Park and Oakland, the famous summer resorts. The scenery along the Baltimore & Ohio route is the most picturesque in America. Pullman accommodations may be reserved in advance of journey. For rates and information apply to nearest B. &. O. Ticket Agent, or Chas. O. Scull, General Passenger Agent, Baltimore, Md.

Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co.

Phenacetine-Bayer

ANTIPYRETIC and ANALGESIC; Prompt, safe and effective in Fever, Influenza, Rheumatism, Neuralgia, Pneumonia, Cephalalgia and all forms of pain.

Phenacetine is given in doses of 2½ to 10 grains, 3 or 4 times daily. It does not depress the heart.

Phenacetine is supplied in ounces, also in tablets and pills, alone and with Salophen, Sulfonal, etc.

Sulfonal-Bayer

HYPNOTIC and SEDATIVE; Indicated in all the Insomnias including those of insanity and the Neuroses; Causes no nervous or gastric disturbances. Must be given as directed.

The dose of Sulfonal varies from 15 to 45 grains; It should be given an hour or two before bedtime.

Sulfonal is supplied in ounces, tablets and pills; also in tablets in combination with Phenacetine.

Other Farbenfabriken Products:

Salophen, Trional, Aristol, Losophan, Piperazine-Bayer, Europhen.

New descriptive Pamphlets on these Preparations mailed by

W. H. Schieffelin & Co., New York.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia. Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

NO WAX

Is used in our **Hollow Suppositories.** Made from purest **Butter of Cocoa only,** which **melts** at the temperature of the **body.** Can be filled with any medicine. Anal, Nasal, Urethral, Cystic, Vaginal, and Intra-Uterine sizes.

Also, Ricord's Solid Suppositories for Gonorrhœa, and Nelaton's Solid Suppositories for Constipation and Piles. Samples sent Free on application and mention of this paper.

HALL & RUCKEL,

218 Greenwich St. New York City.

MARLIN SAFETY

REPEATING RIFLES

Made in all styles and sizes. Lightest, strongest, easiest working, safest, simplest, most accurate, most compact, and most modern. For sale by all dealers in arms. Catalogues mailed free by

The Marlin Fire Arms Co.,

NEW HAVEN, CONN., U. S. A.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

THE TREATMENT OF GASTRO-INTESTINAL CATARRH IN CHILDREN.*

J. MADISON TAYLOR, M. D.†

Many authorities on children's diseases still retain the term "functional disturbances of digestion," including vomiting, simple diarrhœas, etc., and defining these as being without lesion. Others, again, as Louis Starr, regard all catarrhal states as practically involving a lesion, although a very transitory one and generally non-demonstrable post-mortem. In an extended experience in these disorders it has seemed to me wiser to regard them all as dependent upon the lesion of an active catarrhal process whether that be temporary or involves structural changes.

ACUTE GASTRIC CATARRH OR PERSISTENT VOMITING.

A very common disorder of infancy arising from irritative conditions of the stomach, or accompanying manifestations of acute disease, such as the exanthemata. The most common cause is unsuitable food whether due to some disturbances of the mother's milk—in which case it is necessary to regard the mother as the avenue of treatment—or, in hand-fed children, to any of the numberless opportunities for causing damage which arise in the preparation of artificial food.

The *symptoms* are chiefly those of discomfort, listlessness, lack of appetite soon followed by vomiting of fermenting substances, curdled milk or whatever the stomach may contain of food residue along with mucus. There is likely to be some fever, an acceleration of the pulse, tenderness over the epigastrium, and all these symptoms may last for thirty-six or forty-eight hours. In a vigorous child the whole episode often passes with a gush of loose fæces.

If it may be definitely ascertained that there is nothing behind all this the simplest treatment only is necessary to bring about a cure with the utmost promptitude. The essential indication is to neutralize the hyeracidity of the stomach, due to organic acids, and possibly the employment of a mild laxative. The important elements of treatment consist in thoroughly investigating the condition of the food supply—for example, the health of the mother and the quality of her milk and correcting whatever faulty conditions may prevail. Watch must be maintained if a specific trouble threaten. It is well to bear in mind that the specific fevers very rarely arise in a child under six months of age.

CHRONIC GASTRIC CATARRH, OR PERSISTENT OR RECURRING VOMITING.

Here there is a distinct hyperæmia of the gastric mucosa which membrane gradually becomes thickened and loosened, changing in color and voiding sticky mucus, or at times even some little mucopus. The gastric secretions are lessened,

*Read Before the Atlantic County Medical Society at Atlantic City, May 3rd, 1893.

†Professor Diseases of Children, Philadelphia Polyclinic, Assistant Physician Children's Hospital and to the Infirmary for Nervous Diseases, etc.

certainly in efficiency, and considerable depression of health obtains. The largest number of cases arise between four and seven months, coinciding with, if not dependent upon, the development of the first teeth.

The causes responsible are whatever influences lower vitality—poor hygiene, early weaning, or, above all, bad hand-feeding. As a matter of fact, the mother who is capable of nursing a child is a very rare animal, not only because of incapacity to secrete a wholesome quality of milk or maintain this for any length of time, but especially in that the modern mother, unless under most exceptional circumstances, is subject to numberless disturbing causes—physical and particularly emotional—and many the result of necessity such as over-fatigue from laborious occupations. Any of these, or more likely all together, soon inhibits the average mother, in the upper classes even more than in the lower, from maintaining a suitable food supply for her offspring. I have several times seen children die in a very few hours from profound disturbance of a mother's emotions.

Next we have to deal with poor milk even though it be good originally. Milk is subject to such an array of deteriorating influences that it is most dificult to place it before the little consumer in anything like a respectable condition. As to how milk should be cared for from the beginning I will speak further on. The bottle-fed infant must, above all things, have the bottles kept absolutely clean. Nor is this so difficult a matter if certain very simple rules are clearly laid down by the physician. My directions to mothers at the Dispensary of the Children's Hospital and at the Polyclinic Hospital, where the service is a large one, are usually printed and handed to them, and are as follows: There should be in use at least three bottles and a half dozen short rubber nipples; a common kitchen bowl filled with a solution of bicarbonate of soda in boiled water. One bottle should be in use; another standing near the fire filled with the soda solution and a third bottle drying in a sunny place. The extra nipple should be floating about in the soda solution. These to be used in constant rotation, cleaned out each time, rinsed with the alkaline wash and treated as described. The long flexible tube has happily been almost banished from every civilized community.

In children under eight months, no farinaceous foods are suitable, not even the digested starches; only the animal foods are safe for such young infants—either milk in some form, or broths. It should be known to every mother that children are incapable of digesting starch foods until nearly a year old, but, alas, many medical men fail to bear this sufficiently in mind.

The dangers of the subacute catarrhal state of the stomach in infants are very great, not only from death from exhaustion, but from the profound depression of vitality, leaving them fertile ground in which the seeds of disease may flourish.

The treatment depends almost entirely upon the regeneration of the food conditions. A thorough investigation of the quality of the milk when it comes to the house, strict inquiry into the vessels which contain that milk after it has been received, complete isolation of this from any filthy odors or volatile principles which may contaminate this very sensitive fiuid and, finally, such treatment of the milk as the condition demands.

Treatment of the milk may oftentimes, with advantage, consist of sterilization. Sterilization has been drummed into the heads of the medical people, and into the minds of the laity likewise, as being the greatest panacea and cure-all for every childish ailment—a preventive of all threatened diseases, even of tuberculosis. These great hopes have been by no manner of means fulfilled. Sterilization, or the bringing of milk up to a heat just short of boiling, thereby destroying contained germs and otherwise producing conditions which make the milk more readily accepted by an irritable stomach, is a very valuable measure, with this inevitable proviso: *Whenever the occasion for its use has passed by, let there be as speedily as possible a return to good cow's milk unchanged.* Sterilized milk will not maintain a child for any considerable period in the same degree of vigor, nor with proper increment of growth, as will normal milk. Indeed, as Professor Albert Leeds has recently pointed out, the varieties and numbers of bacteria in milk are far less than the public have grown to believe. Tuberculosis sometimes does insidiously reach the unsuspecting victim through

this avenue but rarely, very rarely. Other microbic dangers do exist in milk, but not nearly to such an extent as we medical men have been teaching or have been taught. The method of *Pasteurization*, or heating milk up to about 150° Fahrenheit, does nearly all that may be reasonably required, unless the milk supply is distinctly suspicious.

A good method of preparing the day's supply of milk is to take half a dozen stout pint bottles, thoroughly cleanse and fill them with the milk, and stopper them with absorbent cotton thrust into the nozzle. These are to be placed in a pan of water and the water brought to a boil for about ten minutes. This drives objectionable gases from the milk and kills all ordinary forms of bacteria. The cotton prevents the re-entrance, at least for a long time, of germs floating in the air. These bottles put upon the ice, furnish very respectably prepared rations for a child.

This milk diluted somewhat with boiling water for the very young, or not at all for those of nearly a year, guarded perhaps by a little alkali, as lime water, will do for a healthy infant. If the digestion be weak, or, as in the matter under consideration, markedly disturbed, other conditions may be maintained. Among the best of these, to my mind, is peptonization by the cold process as recommended by the Fairchild firm. Two grains of extract of pancreatine and five grains of bicarbonate of soda rubbed up with a tablespoonful of milk, then the proportionate amounts of milk and water added to fill a six ounce nursing bottle, and all this plunged in hot water until the milk be somewhat warmed, then slowly and cautiously administered about every two hours, will usually suffice.

It is a rule abundantly confirmed that fresh cow's milk is much better than any artificial preparation, but it is also a matter of experience that it is frequently impossible to get good, fresh, sound cow's milk and we are inevitably driven to the manufacturing chemists for an alternate.

Among these may be mentioned malted milk, which I have known to prove of very great service. A family of three children under my direction, in a place where good, fresh cow's milk could not be had, were brougbt up upon malted milk and water and nothing else, from birth until a year of age, and they are very vigorous well-developed children to-day.

Ordinary condensed milk contains a great excess of cane sugar, which readily undergoes acetic acid fermentation and should be avoided when possible, but even for this a good word must be said, because it is a matter of experience that many times, when driven to the use of this imperfect substance, children not thriving on what should have been a better food, do surprisingly well.

Again, while theories would seem to show it impossible, it is known that babies have been raised in fairly good shape, upon so contemptible a fluid as veal or chicken broth and survived to be a credit to their race.

Skin Conditions.—The bath is important, but in very young babies the medium need not always be water. For several years, while attending a considerable number of dispensary obstetric cases I pursued the plan of having all children bathed in clean sweet oil and not water, and the results were eminently satisfactory. Bath-chill was thus averted and the irritations caused by varying qualities of soap, etc., were spared the youngster and I believe that when this line is pursued, better results are had than by the use of soap and water.

My own children were treated thus until three months of age and the nurse admitted that the trouble was less than with water and stoutly averred that the children's skins were much better.

Clothing.—The normal clothing, at least the under-clothing, for an infant is wool or possibly silk, summer and winter. No other fabric is safe. The vicious habit of exposing little babies' legs to the sudden changes of our American climate cannot be too sweepingly condemned. Undoubtedly many children survive such maltreatment, but it can with equal certainty be demonstrated that this baring of the knees and arms invites surface chill which results in our American catarrhal stomach. Far worse, since maternal vanity is responsible for many tiny graves.

In this gastric catarrh there is usually a subnormal temperature in the late reaction from the feverishness which often arises, and in this condition of depressed vitality, where the heat-making power is less and where the accompanying leaky skin expedites the loss of body heat, chill

of the internal organs is almost inevitable. Thus, little increments of hyperæmia are caused in the internal organs which may seem trival but almost certainly do damage to the alimentary tract.

GASTRO-INTESTINAL CATARRH.

This condition prevails largely among children who have passed the first dentition, and may be divided into the lesser *Indigestion*—a disturbance which comes and goes—and the greater *Mucous Disease.*

A gastro-intestinal catarrh may arise in a robust child and, with little or no treatment, speedily subside. In children who are less resilient, or more locally susceptible, this becomes a fixed condition called originally by Eustace Smith, of London, by the excellent name *mucous disease*, and must receive special consideration.

To begin with *indigestion*, or gastro-intestinal catarrh. The causes are many: unfavorable surroundings, deficient light and air, too little of out-door exercise and too much of school or in-door coddling, and along with the undoubted susceptibility which exists at the time of the eruption of the permanent teeth, injudicious food and insufficient clothing, all conspire to bring about a very common and troublesome malady of childhood. This disorder prevails less in summer than in winter because there the conditions of life of the average child are simpler and more wholesome. The out-door exercise, so needful for the young, keeps the blood upon the surface of the body and the circulation is more uniform. There are more reasons than can be enumerated here for the necessity of open air exercise in maintaining the ebb and flow of the vital activities.

The chief cause, however, of gastro-intestinal catarrh is coarse, indigestible food. This acts as an irritant upon the mucous surfaces which may already have suffered some depreciation due to these remoter causes depressing vitality enumerated above. An excess of mucus, which in itself is an active ferment, is poured out; hence arise fermentative processes and the resultant organic acids. These, along with masses of coarse food, irritate the intestine and a long train of disturbances result. An attack of vomiting and purging may arise which for the time being clears out both stomach and intestine. Unless the causes are removed and the food more carefully selected, it recurs again and again. The mass of mucus mechanically interferes with the absorption of the digested material, the blood is insufficiently replenished and hence the organic activities are lowered and the gastric and intestinal juices deteriorate. Thus is there direct and indirect reaction.

Extension of the catarrhal processes from the air passages is frequently an avenue of mischief, and I have often seen children and adults as well, in whom an acute attack of vomiting and purging would follow cold in the nose. Sufferers from this trouble become spare, flabby and pale, with a leaky skin, rough and inelastic to touch; a weak pulse, with irritable heart; tongue marked by the teeth, literally "indented;" the tonsils are likely to become hypertrophied; the sluggishness in secretions causes vitiation, and hence arises the mawkish odor of the breath; the cervical glands are enlarged; the belly becomes prominent or depressed alternately, a certain amount of pain occurs along the track of the colon, especially where sharp turns are made, as in the right and left hypochondrium; rumbling of gas in the intestines, and a generally variable and capricious appetite.

MUCOUS DISEASE, OR CHRONIC GASTRO-INTESTINAL CATARRH.

A troublesome disturbance of digestion which arises after the first dentition. *Mucous disease*, is to my mind an excellent name for a condition extremely prevalent among American children. Many times not recognized, it is a fertile source of serious mischief.

The lesions are similar to those of *indigestion* but much more severe and extensive. It is usually seen between three or four and twelve years of age—during the establishment and completion of the second dentition. Starr points out that it is especially the resultant of whooping-cough. While there is a considerable number of scoffers, and among them, too, some able men, who love to insist that "teething" produces nothing but teeth, undoubtedly there is a profound disturbance of nervous balance during this period, at least when the eruption of a tooth or teeth, is imminent. The hyperæmia of dentition seems to be reflected throughout the length of the alimentary

canal. Certainly *something* produces increased secretory activity and greater susceptibility to irritants.

The causes enumerated under *indigestion* also obtain here.

The symptoms are those of indigestion magnified and persistent. A steady emaciation prevails; the muscles fall into a condition of pitiable weakness; curious vaso-motor conditions occur; pallor, occasionally varied, especially in the afternoons and under conditions of excitement, by circumscribed flushing of one or both cheeks is noticed; along with this there may be pallor of the lips; this pallor may alternate with cyanosis, until the child looks as if it might faint at any moment, indeed, a very little excitement or fatigue will cause it to do so; the skin is usually sallow, leaky, and flabby to the touch; in places a mild pityriasis occurs and little branny scales fall from the surface; the hair grows lustreless, and in vivid contrast to itself in health; the oral mucous membrane is seen to be pale; the tongue presents a peculiar and pathognomonic variation known as the "glazed tongue;" —the organ is seen to be flabby, "indented" by the teeth, a furry coating over most of the surface except the edges and tip which are reddened, and in the middle an ovoid patch of glistening surface which looks as if it had been shaved. Here and there about the surface fungiform papillæ, brightly reddened, show strongly through. At times, especially after a stormy period of vomiting and purging, a second appearance comes upon the tongue, which is known by the name of the "worm-eaten appearance." Here the organ is not so flabby, is more of its normal shape, the furring not so extensive, but more uniform and thicker, and the characteristic worm-eaten appearance is an irregulrr denudation here and there about the surface just like an old, worm-eaten bit of wood, the surface of which is bright red with sharp-cut edges where the coating outlines it.

Curious mental states often prevail during this disorder; exceeding capriciousness of temper, for which the child may be unwisely punished; morbid cravings; absurd fancies which take the color of the child's temperament, with such variations as its accidental training may cause. A characteristic point also is the tympanitic belly which is almost constant about an hour or two after food; and now and then in the early morning an umbilical colic. Constipation is the rule, and when this is overcome, is very likely to alternate with painful tenesmus.

The nights are periods of horror with unrestful sleep, terrifying dreams, sometimes actual walking expeditions which, in fact, are rarely causeless. The urine may be passed unconsciously. Again, grinding of the teeth at night and the picking of the nose by day, produce a picture which old women gravely insist is due to but one lubricoidal cause. As a matter of fact, worms are rare nowadays, at least in my experience, much more so than formerly. I can distinctly recall the time when it was a common thing to dislodge ascarides, but now it is less frequent although suitable remedies may be applied as tests.

The temperature is rarely disturbed. It may, however, be a little high, especially after undue fatigue, and is, in a certain sense, an index or nerve tire. Another characteristic point is a prevalent irritative cough quite independent of any pulmonary involvement.

Treatment.—The treatment is much the same as that of indigestion, except that in indigestion the results are soon obtained, whereas in mucous disease it is imperative to regulate the entire environment and conduct of the child for a much longer period, even for months. The indications are to stop the fermentation of the food, and to give this in regulated amounts and at definite intervals. No starch foods should be taken, except carefully guarded bread. Fresh bread is indigestible because of the continued activity of the ferment. After some hours this ceases to be. Also the subjecting of bread to a second heating kills this ferment and makes it more wholesome. Therefore, a re-heating does nearly as much as toasting without the objectionable effect which toast has upon the bowels. The hours for feeding had best be systematized thus: Breakfast at seven, a light meal or "tiffin" at eleven, dinner at half past two and a light supper again at seven. The food should consist of milk either guarded with a little lime water, or peptonized by the cold process; broiled meats, beef and mutton and rarely a little chicken; soups well-freed from fat; oysters occasionally; purees of clams, oysters, or fish. The green

vegetables well cooked—such as asparagus, spinach, stewed celery, cauliflower tops with every other day a soft boiled egg for breakfast, or an egg boiled very hard and the yolk spread on bread are suitable. Butter is best omitted, but an excellent substitute is the yolk of a lightly boiled or poached egg spread on bread. It is well to make such variety as is possible by using different kinds of bread,—rusk, rasped rolls, etc. The meats should be well selected, tender, and the fat carefully removed. As the child improves, stewed dried fruit with very little sugar, or a baked apple may vary the monotony, but the best dessert is the innocent preparation known as junket—milk curdled with rennett, calves' foot jelly, or possibly a plain rice pudding.

The clothing should be very carefully inspected—a flannel band about the abdomen to begin with, and *always* wool next to the skin. The outer clothes may be light, especially in warm weather, but the surface of the skin must be protected by a thorough non-conductor, always wool or possibly silk. The skin must be kept in good condition by bathing. In this it is well to use, rather than soap, salt, which is amply cleansing and more stimulating. A second treatment of the skin should be had after the mid-day exercise, in the shape of a rubbing down with a coarse towel, or what is extremely good, a salt towel. This consists of an ordinary crash towel dipped in a strong salt solution and dried. Exercise is important to regulate carefully. Where the child is very weak this should be at first altogether passive by means of massage, either professionally done or at the hands of an ordinary nurse who could easily be taught the simpler movements. Later small increments of exercise may be prescribed, such as are had through the Sweedish remedial movements, and, as strength increases, out-door movement in the form of driving interspersed with short walks. After exercise of all kinds a brief period of absolute rest must be observed—a quarter or a half hour at least. Exercise tends to keep the blood upon the surface and to excite a more active ebb and flow. It also stimulates digestion and works many other advantages, provided always it be judiciously regulated and even supplemented by ample rest.

The medicines are of less importance. The first indication is to check the output of mucus, the next to neutralize the acids and prevent their formation. The alkalies are useful here, producing several effects, partly sedative and partly aiding to dissolve the mucous mass. Next comes the restoration of the irritable mucous membrane and to bring back the normality of secretion. Here aids to digestion and digestive ferments can be combined. Finally, the bowels need careful regulation. In my dispensary work we use two or three simple prescriptions which seem to be entirely efficacious. The first of these is bicarbonate of soda and infusion of gentian. Curiously enough, children object very little to this nauseous dose and administered before meals it is wonderfully effective. If great objection prevails, a drop of nux vomica to five drops of glycerine, along with the bicarbonate of soda, is better taken. Syrups are to be avoided, and yet the following mixture also has a valuable function. Bicarbonate of soda, nux vomica, spiced syrup of rhubarb and water, make an excellent combination, taken before the three principal meals. The clearing of the bowels, where this is needed, is best done with castor oil, although if the activity of the liver is manifestly impaired, a little calomel may be used with advantage, or the tasteless phosphate of soda, or, again, chloride of ammonium persistently used. To restore intestinal tone, and keep the bowels regularly moving, either myrrh alone, or tincture of myrrh and aloes, serves a useful part. I usually tell my students that the most important agent in treating these disorders of the digestion is a pencil and a good sized sheet of paper. For thus can one write out at length the conduct of the child for the entire twenty-four hours, specifying the hour for medicine, for food and for exercise, the time of bathing, the length of the exercise and the rest, making clear that these shall not be unduly near the feeding time, outlining exactly what foods may be taken and what avoided, and thus alone can the best results be had. I might speak of endless drugs which have, no doubt, their uses, but I think it would be of questionable value.

I close this summary with a few remarks on the preparation of foods for children.

First, of mother's milk. I wish I

could believe that mother's milk was the best food for a baby. It ought to be but it is not. By this I mean that it so rarely happens that a mother is both a good mother and a first-rate cow, that one stands among the rarities. In the lower walks of life the mother has not only large drains upon her through unavoidable physical labor, but has responsibilities, in the bearing of which variations arise which reflect themselves upon her milk. If she content herself with simply being the mother and caring only for the baby, as in the case of a well-paid wet nurse, that would be quite a different matter. A wet nurse is able to be many times better than a mother. The mothers of the upper walks of life have also many drains upon them, chiefly emotional, and they, too, fail many times, but not necessarily oftener than the poorer ones, although the contrary notion prevails. The wet nurse, theoretically the best supply of food for a baby, is seldom much better than is careful hand-feeding. So, when all is said and done, thoroughly careful hand-feeding is about the safest and most reliable.

When the milk of an animal is the aliment, much care is needed from the time it is removed from the cow until it is used by the child. Two or three practical points may not be amiss. Milk from a healthy cow may be used instantly it is drawn or else not until it has been subjected to a primary chill. It contains certain volatile principles which, if not removed, are partly poisonous. After being drawn, milk should instantly be placed in a temperature of 60 or 65 degrees, in a clean atmosphere free from all objectionable odors, and there allowed to remain until quite cool. Thus are the gaseous principles expelled from it and in other ways it is rendered more wholesome. When received by the consumer, it should be put carefully in an hermetically sealed vessel and in a cool place, not necessarily the refrigerator, which usually contains butcher's meat or other materials which may give forth offensive smells, but kept apart by itself, if merely placed in the shade where a good draft blows, and it is cool as in an ordinary cellar. In very hot weather it is well at times to employ sterilization, but this should never be continued any length of time, because sterilized milk does not maintain the health, nor is it competent to form the best of muscle and other structures. Under conditions of stress, pasteurization is usually sufficient.

Variety. No matter how judiciously a child with weak digestion be fed and how admirably the regimen outlined seems adapted to his needs there comes a time when he needs change and variety. As the changes in the digestive capacity grow rapidly in the earliest years, care must be exercised to liberalize the dietary consistent with the constitutional demands. A typical illustration of this came under my notice at Bar Harbor last summer. The child, aged three years, of a gentleman who was himself a patient of mine had been ill and was carefully directed by a physician of the highest ability to live on a prescribed diet and throve abundantly. This was continued for many months with unvarying regularity. After a time for no discernable cause the boy failed, grew irritable, seemed weak, easily tired; began to void uric scid, the skin grew flabby and leaky. The change of air had done nothing for him and the parents were in despair. A careful search into the matter revealed the wretched lameness of a diet suitable to a child of a year younger and consisted of milk, soups an egg alternate days and zweibach; varied only with junket and rice pudding. In the face of the morbid fears I enlarged this by the addition of a few green vegetables, roast and broiled meat once daily, a little fish and some stewed fruit and promptly the whole picture changed.

Palpitation.

Examination Physician of Insurance Company—What did your father die of?

"Palpidation ohf der heart."

Physician—Mother?

"Palpidation ohf der heart."

Physician—Two brothers?

"Palpidation ohf der heart."

Physician—What Caused it?

"Dhey each bought a lottery ticket and missed der big prize."

JUSTICE.—"Officer what is the prisoner charged with?" Officer Lafferty—"Well, your honor, I'm not a judge, but it smells to me a good deal like whiskey."—*Exchange.*

CLINICAL LECTURES.

HEART STRAIN, PROPHYLAXIS AND TREATMENT.*

CHAS. G. STOCKTON, M. D.†

In speaking of typhoid fever, I have told you that one of the most important matters to be borne in mind concerning convalescence is the condition of the heart. Many persons who recover from typhoid fever are hampered with weak hearts, and it is our duty always to examine carefully into this point and not to allow patients to return to work until we are certain that their hearts have regained fair strength.

This patient came early in January. His case was one of "walking typhoid"—probably in the third week. At the time of his admission to the hospital he had a temperature ranging between 103° and 105°, and continuing thereabouts for three weeks longer. Before his fever had disappeared his heart was found to be weak. It was stimulated with large doses of brandy, digitalis and strychnine, but, at certain times, it seemed impossible to keep it beating. In the latter part of February his pulse was 40 to the minute, very weak, intermittent and irregular. A little later the pulse fell to 35. For two weeks it ranged between 60 and 30, and at one time it fell to 18. The sounds were indistinct and it was almost impossible to feel the pulse at the wrist. It was only by the use of heat and friction to stimulate the capillary circulation and by the internal administration of liberal doses of heart stimulants that the patient was kept alive.

Under steady stimulation the pulse has been restored nearly to normal and is now beating at the rate of 60 or 75 to the minute, while the heart sounds are fairly good. This man, however, will have a weak heart for a year at the best, and, during that year, he should not be allowed to engage in hard work. If he does he will become one of the unfortunate individuals, and there are many such, who go through life with strained hearts.

Another patient, who comes to me from Pennsylvania, is a woodsman, engaged in lumbering and other forms of active exercise which should make him strong and vigorous. At the same time, however, he has overstrained his heart, and, as a result, it has not been able to fulfill the demand which the body has made upon it. In spite of tonics and general treatment which various physicians in Pennsylvania have given him, he has suffered from vague symptoms of weakness and discomfort without really knowing what was wrong with him.

On admission to the hospital, his heart was slow and weak, its first sound almost inaudible, and there was a general weakness without signs of other organic diseases. I put him to bed and have kept him there, allowing him to get up now only for the special occasion of appearing before you. He has had heart tonics, digitalis, strophanthus and, especially, strychnine.

If I could do for him exactly what I should like, he would be kept on his back for two or three months with faradism every day, with massage, friction and hot footbaths to bring the blood to the surface of the body and stimulate the capillary circulation. The same plan of treatment should be resorted to in this first case of convalescence from typhoid fever, if the heart does not return to its normal condition; for, although this heart has not been strained, it is weak following the cloudy swelling and fatty degeneration that so commonly occurs in severe infectious diseases.

Overwork, loss of sleep, long watching, grief, excitement, may bring about strain to a perfectly normal heart and after a long siege of typhoid fever, there is often harm done in allowing a man to go back to his routine work, which usually means the necessity of overdoing and of overstraining an already weak and susceptible organ.

*Delivered at the Buffalo Co. General Hospital.

†Prof. of Principles and Practice of Medicine, University of Buffalo.

This third case is also one of convalescence from typhoid fever. The patient was admitted January 5, in the beginning of the disease. He was very ill and his temperature ranged from 105° to 106° in the evening, requiring antipyretic measures. His pulse varied from 130 to 140. Finally both temperature and pulse fell, the latter reaching 60, 50, 40 and even 30 to the minute. His heart was sustained when not too infrequent by digitalis and strophanthus and when it became too slow to admit of the use of such drugs, by strychnine hypodermatically, the largest doses being, gr. one-twentieth, often enough to keep the heart going.

This man, as well as the first patient, came near dying from syncope. He was at times unconscious and his extremities were cold. His stomach was intolerant for a time, and he was nourished by rectal alimentation. The condition of debility was relieved by rubbing with alcohol, by hot mustard footbaths and by various internal stimulants. But his heart will remain weak for a long time and he must be advised against active work.

It should be observed that this cardiac depression is far less frequent in those patients who have had the benefit of the cold water treatment as directed by Brand, of Stettin.

There is one other point about which we must be cautious in these cases of convalescence from typhoid fever. We must be sure that the patient does not pass from our hands with the alcohol habit fixed upon him. The use of alcohol has been unavoidable during the course of the disease, and you will readily understand how a patient with a weak heart is much more predisposed to keep up the use of alcohol than is a healthy individual. A man whose heart is so weak that it is impossible for him to exercise either mentally or physically with comfort unless he is sustained by alcoholic drinks, is very prone to form the habit of taking whiskey.

COMMUNICATIONS.

THE ADVANTAGES OF ANTISEPTIC IRRIGATION OF THE PARTURIENT CANAL BEFORE AND AFTER LABOR.

T. RIDGWAY BARKER M. D.

"To avoid danger is a thousand times better than to prepare to meet it."

Prompted and emboldened by this thought, I present for consideration and discussion the advantages to be gained by the employment of ante-partum and post-partum vaginal irrigation.

Having accepted as proven the role which micro-organisms and their products, ptomaines, play in the development of disease, it has been my practice for the past two years to employ, in cases of confinement, irrigation of the parturient canal.

The results from this routine method have been so uniformly satisfactory, aside from any theoretical considerations, that I would fain persuade every practitioner of obstetrics to give the plan an impartial trial.

While it has, I am well aware no definite claims to novelty, yet the rules governing aseptic midwifery are so generally disregarded in private practice that further study cannot be otherwise than beneficial.

It is certainly a fact that strong antiseptic solutions containing mercury or carbolic acid are likely, and will, if long continued, poison the patient. Garrigues, in his paper on "Corrosive Sublimate and Creolin," published in *The American Journal of the Medical Sciences,* 1889, reports twenty cases of death from this drug in obstetrical practice. But any valuable remedy will fail to give good results if not properly administered. Therefore, its abuse cannot be said, in any way to militate against its use.

The method which has given me the best results consists in having the external parts about the genital region carefully and thoroughly scrubbed with soap and

hot water with the onset of true pains. This is followed by a second cleansing with 1 to 1000 bichloride of mercury solution, the final washing being with boiled water. This completes the toilet of the entrance to the vestibule of the birth canal. As to the treatment of the canal itself, a fountain syringe is filled with one quart of hot, boiled water containing bichloride of mercury 1 to 5000. The ordinary nozzle made for vaginal use, after being rendered aseptic, is introduced into the vagina and carried up to the anterior vault of the canal, the stream of water having been running freely before introduction, to expel all air from the tube. When about half the solution has been used in bathing this portion of the vagina the nozzle is slightly withdrawn and made to enter the posterior pouch. In this way the whole mucous surface is irrigated, and at the same time some of the overflow bathes the cervix.

It is very desirable to finish this step in the procedure before rupture of the membranes, as their presence tends to prevent the escape of the antiseptic fluid into the uterine cavity and between the uterine wall and decidua. It will be noticed that so far our ante-partum efforts at cleanliness have been principally confined to the vagina, and this is the point to which our attention should be principally directed, for the source of infection is far more likely to lurk here than in the pregnant uterus.

The vaginal douches are to be administered with the female in the semi-recumbent posture, in order that free drainage may be secured and no fluid permitted to collect behind the posterior margin of the vulva. The antiseptic irrigation is to be followed by a free bathing of the parts with boiled water, so that absorption of the mercury may be rendered impossible. By these means we run no risk of mineral poisoning, while we do secure a perfectly aseptic condition of the birth canal.

When can we, without such precautions say, with any degree of certainty, this woman's birth-canal contains no gonococci or other noxious germs? Her family life may have been the purest in every particular, yet gonococci may be present. The occupation of the husband, as Lapthorn Smith, of Montreal, has pointed out, through a lack of personal cleanliness may infect his wife. Such occupations as scavengering, rag-picking, and the like, render a man especially liable to infection when the simplest rules of hygiene are neglected. The same author pertinently remarks, "Before labor begins we should disinfect the vagina of all women whose husbands have had gonorrhœa, taking it for granted that all have had it unless we have proof to the contrary."

Some writers, in spite of such facts, declare antiseptic irrigation unnecessary, because, they argue, that Doderlein's experiments, as to the nature of the micro-organisms found in the healthy vaginal canal, prove conclusively that they are non-pathogenic; but I would make answer, that what is harmless in a healthy vagina with a perfect mucous membrane is not necessarily so when its walls have been overstretched and are the seat of lacerations. The science of bacteriology has not yet declared the law that non-pathogenic micro-organisms always remain so under all conditions and circumstances.

Among those who are opposed to such prophylactic measures as I have suggested, may be mentioned Rosenberg, of the New York Polyclinic, who states in a paper published in the *Medical Record*, February 4, 1893—"So far I have not said anything about the prophylactic vaginal douches, and I only wish to speak about them to condemn their routine administration. I do not believe that the vagina can be made sterile, no matter how much douching is done; but I do believe that infectious material is very frequently carried into the genital tract by dirty instruments or fingers."

Now it goes without saying, that if you are going to employ dirty instruments and fingers in your pseudo attempts at aseptic midwifery, you had far better avoid examining the patient at all. In fact, it would be wiser to secure some one else to take charge of the case. Therefore, such an argument is fallacious.

But what is still more surprising is that the same writer in his article, should cite, in support of this view, several cases of puerperal infection in which the women died. They were supposed to have aseptic parturient canals, when in reality septic matter had been introduced by unclean midwives in their efforts to ascertain the female's condition previous to the arrival of the medical attendant.

Here we have a striking example of our inability to distinguish between an aseptic and a septic birth-canal. The life of the woman is thus risked unwarrantably when we have nothing but pure assumption on which to base our opinion.

Some extremists have gone so far as to recommend the employment of vaginal antiseptic injections as early as one week, or more, before the onset of labor, and they advise continuing them until the first stage is well advanced.

This is, perhaps, carrying the principal of antisepsis too far, but better that than not far enough. The importance of having an absolutely clean nozzle to the syringe, cannot be too forcibly impressed. Dirty tools can never be expected to do clean work.

Earle, in a paper published in the Chicago *Medical Journal and Examiner*, tersely remarks, "You cannot carry out intra-uterine injections with a half-ounce syringe and a goose-quill." Were the benefits arising from vaginal irrigation previous to delivery wholly included under the term asepsis, we might rest well-satisfied, but that is not all, for the hot fluid fills a useful purpose in softening the cervix, thereby lessening the pain incident to its dilatation.

Some may urge against the practice, that it washes away the natural mucous secretion which is intended to lubricate the parts and facilitate the passage of the infant, but this is a theoretical objection which has no existence in fact. Quite the reverse one finds to be the case, which is confirmed by Garrigues, of the New York Maternity, who states, in a paper read before the Section on Obstetrics and Gynecology, in 1892: "Personally, I am opposed to rubbing and scrubbing the vagina, as some think necessary, but as to a vaginal injection before delivery, I believe yet, that it is useful. It will remove both dirt and microbes, and if, at the same time it removes a layer of mucus that lubricates the vagina, and, therefore, protects the perineum, it is easy to see that new mucus is poured out in abundance to replace the first."

With an aseptic parturient canal our fears of infection of the eyes of the infant, as it is driven along, are practically *nil*, for there is nothing to give rise to ophthalmia, that terrible disease so fatal to the sight. As my paper does concern itself with other necessary precautions, such as those relating to the clothing and the person of physician, nurse, and patient, no mention will here be made of them.

Having outlined the ante-partum procedure which would seem to recommend itself to the careful accoucher, we have still for consideration some post-partum measures.

Whether the case has been one of natural or instrumental labor makes no difference, all must be treated alike, save the latter class will require extra care and attention, since the doors for the entrance of septic matter are more numerous and wider open.

No matter how skillfully one may have delivered the placenta and secundines, we never can know positively whether everything has been expelled. Let the examination of the placenta be ever so minute, a fragment may be left behind, or a shred of membrane that the eye of the attendant has failed to note the absence of.

Appreciating this fact, it is but fair to assume that there is in every uterus after delivery, a cavity which contains material which, if it becomes infected, will place the patient in great danger. Micro-organisms feed on dead tissue, and by their multiplication pour out ptomaines which, when brought into contact with living cells, cause their death.

Thus is formed the virulent poison which the vessels are ready to suck up and carry through the system. Let the source of the pathogenic organism be what it may, we do know that when it takes up its residence in the utero-vaginal canal it is a terrible enemy to do battle with. Therefore, it would seem but reasonable to institute prophylactic measures to prevent the entrance and development of these breeders of disease, which can best be accomplished by the employment of antiseptic irrigation.

Mercury in the form of corrosive sublimate is scarcely suitable for post-partum vaginal irrigation, since it is so readily absorbed by abraded surfaces. Hence, carcolic acid, creolin, boric acid or peroxide of hydrogen are to be preferred. The advisability of resorting to irrigation immediately after labor is questionable, since the likelihood of inducing hemorrhage, introducing air, or irritating fluid

into the yet unsealed uterine sinuses is possible.

After the lapse of twenty-four hours, however, I would recommend a vaginal douche of carbolic acid, one drachm to the pint, or creolin, one per cent., followed by an equal quantity of boiled water.

It would appear from the clinical symptoms of puerperal infection, that the first manifestations occur on the third or fourth day, in other words, the lochial discharge in the first twelve hours is so free that no contamination by micro-organisms is possible, but on the second day, the discharge not being so abundant, the germs gain a footing, and after a lapse of twenty-four hours pour sufficient poison into the blood-stream to jeopardize the life of the female.

Earle quotes Bakelmann, as deeming intra-uterine injections indicated when, forty-eight hours after birth, the temperature rises to 101.5°F. to 102.2°F., with frequent pulse, without a recognizable cause for it; also, when fragments of placenta and membranes remain in the uterus as a cause for disturbance, and when symptoms of infection of the endometrium are present.

Of course he does! Who would not under such circumstances? But where is the wisdom of waiting until these disintegrating masses become infected before bringing about their expulsion? Why, indeed, delay in removing the oil-can, so to speak, from the neighborhood of the fire when experience unmistakably teaches us that it will explode if only left there long enough? Let us, at least, be reasonable and hasten with all judiciousness to place beyond reach the dangerous element.

If our knowledge of septic processes is worth anything, it surely ought to convince us that disintegrating organic matter has no place beside the living, and the wider the range of separation the safer for the individual. When we resort to vaginal irrigation at the expiration of twenty-four hours, we find the canal in a condition suitable for such a procedure. If the amount of carbolic acid does not exceed one drachm to the pint of warm water, and free drainage is secured, surely no poisoning is possible. Too much stress cannot be laid on the importance of having the female occupy a semi-recumbent position so that the escaping fluid may tend to gravitate toward the patulous vulvar orifice. The pressure by which the solution is forced into the passage should be as low as possible, the object being to irrigate rather than inject.

As is well known, when the woman lies on her back the discharges accumulate at the posterior and inferior portion of the vagina and form a pond well-suited to become the feeding ground for pathogenic organisms. By destroying this nest, which antiseptic irrigation accomplishes, we stop the production of ptomaines and relieve the system of further danger from infection. Appreciating, therefore, the great advantages and the increased safety to the parturient, can we do better than adopt for our motto in obstetrics, and carry out in practice—"CLEANLINESS FIRST, LAST, AND ALL THE TIME."

FRACTURE OF SCAPULA FROM MUSCULAR ACTION.

P. V. HOOVER, M. D., BOONVILLE, IND.

Mr. G. T., æt. 30 years, who while scuffling with a man that was about forty or fifty pounds heavier received a fracture through the body of the right scapula. He said he threw his antagonist over his shoulder his hold suddenly breaking; and as the muscles relaxed he felt something give way on the posterior portion of shoulder. Physical examination revealed marked crepitus through body of scapula. I applied a pad over scapula and held it in position with the usual dressing. Union was rapid and perfect, and there has been no inconvenience since.

I have related the case to a number of physicians and surgeons, and they have all told me that they had never heard of a like case. I therefore report it thinking that its rarity might make it interesting.

SOCIETY REPORTS.

THE CLINICAL SOCIETY, OF LOUISVILLE.

Stated Meeting April 4, 1893.

THE PRESIDENT, Dr. I. N. Bloom in the Chair.

TUMOR OF THE BREAST.

DR. W. O. ROBERTS: I have had a run on malignant diseases of the breast in the last week, having had four cases, the last of which was operated upon to-day, all of them being patients sixty years of age. The tumor removed to-day was first noticed three years ago. Some two months before the lump was detected the lady had a fall, striking her breast against a chair, which gave her very little pain, still she seems to attribute the trouble to that blow. She tells me that the breast a year ago was very much larger than at the time of its removal to-day. It has given her a great deal of pain. No enlargement of the glands in the axilla could be detected prior to operation, but after the space was opened I found two glands that were about as large as a hazel nut. It has all the characteristics of scirrhus—retraction of the nipple and hard, indurated feel of the tumor—and it will be seen upon examination that the muscle seems to have become involved in the growth, the muscle drawn up, as it were, into the tumor. The greater part of the pectoralis major muscle was removed and the axilla thoroughly cleaned out, not only all the glands, but all fatty tissue, leaving the vessels and nerves exposed.

DISCUSSION.

DR. J. M. MATHEWS: Do you ever remove the glands in the axilla unless you can feel that they are indurated or enlarged?

DR. W. O. ROBERTS: I take them out always. Unless this is done I think the operation does not hold out much to the patient, and recurrence is apt to take place quickly.

DR. J. M. MATHEWS: The reason I asked the question is that I have seen quite a number of operations for excision of the breast where the operators paid no attention to the glands of the axilla unless an enlargement can be felt.

TWIN PREGNANCY—DEATH OF ONE FŒTUS AT FOUR MONTHS, THE OTHER BORN ALIVE.

DR. J. M. KRIM: Twelve days ago I was called to attend Mrs. T. in her third confinement. The history of the case is that she gave birth to twins the first time, second time single and this time when I was called she said she had "about three weeks to go." I made an examination and found her in the first stage of labor; I remained seven hours, I think, and the child was born matured but rather small, weighing about 6¾ pounds. A few days afterward I was telephoned to return at once as the patient was suffering with terrific pain; I went back, made an examination, and found protruding through the os something soft, after making slight traction, it ruptured and a very fœtid substance came away shortly afterward which proved to be a macerated fœtus at about the fourth month. The uterus was thoroughly douched and cleansed out, and the patient made an uninterrupted recovery.

The reason I report the case is to get the opinion of the society as to whether this was a twin pregnancy, or a subsequent pregnant condition. The child delivered on my first visit is still alive, apparently not fully grown, was about the eighth month. The fluid which came away on my second visit seemed to be perfectly clear but had a very fœtid odor.

DISCUSSION.

DR. I. N. BLOOM: How long had the patient been married and what were the intervals between the various pregnancies?

DR. J. M. KRIM: Married eight years. First delivery fifteen months after marriage; second four years after the first, this being the third which is about three years after the second.

DR. D. P. SATTERWHITE: I do not think there can be any doubt but both

impregnations occurred during one coition. It is proven according to Gaston that there are never true twins unless they are enveloped in the same sac.

Dr. W. O. Roberts: Do you know if there was at any time during pregnancy any uterine hemorrhage?

Dr. J. M. Krim: This patient belongs to the working class, and said that one time while sweeping she felt a peculiar pain which lasted probably two or three hours; after that she felt nothing more of it. She said, of course, that she felt some pain occasionally, but attributed it to the condition she was in as she had noticed the same pains in previous pregnancies.

I am of the opinion it was a twin pregnancy, two placentas, but why one ceased to grow at four months and the other go on to nearly full term, I am unable to say.

EPICYSTOTOMY FOR REMOVAL OF CATHETER FROM THE BLADDER.

Dr. W. O. Roberts: I performed an epicystotomy week before last on a man sixty-five years of age; the history was that he had some trouble in passing urine and had to occasionally use the cathether to empty the bladder. He was a hard drinking man and three weeks before I saw him he had occasion to use the catheter which he said had not been necessary for some months before, and after introducing it into the bladder it broke off. He said it was one of those red rubber instruments and he was in hopes that he would be able to pass the piece that was left in the bladder, but this did not occur. Violent cystitis developed and his physician consulted me on the subject. I told him the only thing to do was to perform a cystotomy and remove the portion of catheter. The patient came here and I intended keeping him in the infirmary for a few days to prepare him for the operation, but he said he would remain at the hotel until the preliminary treatment had been carried out. In the afternoon (Tuesday) I went to the hotel and found that the patient had gone to the infirmary; when his son had come to my office to consult me about the operation, the old gentleman had gotten on a big spree, and the boy took him immediately to the infirmary. Tuesday evening he was very drunk; Wednesday he sobered up and we managed to keep him in the house until the next day when I operated. I removed from his bladder two pieces of catheter, one about two inches and the other one inch in length, and each piece was heavily coated with salts from the urine—I suppose the coating was at least $\frac{1}{16}$ of an inch in thickness. They were not broken in the attempt to remove the fragments during operation, because they were entirely covered with this coating, showing that there were originally two pieces in the bladder. The technique of the operation was about this: A rubber bag was introduced into the rectum and distended with air, then the bladder was filled with air, then the bladder was filled with water —I say filled, eight ounces being put into it—then an incision made and bladder opened. The incision was made a little too low; I got in front of the point where I wanted to open the bladder and went into the upper wall of the prostate. I recognized this fact simply by the considerable amount of hemorrhage at the time. I carried my incision into the bladder, removing the two pieces of catheter and the man recovered without an untoward symptom, and without the slightest elevation of temperature. He was up on the sixth day sitting in a chair. He now spends most of his time sitting at the window in his room at the infirmary.

DISCUSSION.

Dr. I. N. Bloom: How did you treat the bladder wound afterward?

Dr. W. O. Roberts: After removing the catheter I washed the bladder out very thoroughly with hot boric acid solution then introduced a strip of iodoform gauze draining the bladder in that way for twenty-four hours, then took the gauze out. Did not use any sutures in the bladder at all, or in fact anywhere.

Dr. I. N. Bloom: I was connected with a case of epicystotomy a few days ago in the role of consultant, another gentleman doing the operation. Dr. Schachner asked me to see a case in consultation, the patient giving unmistakable clinical history of stone. He had not up to that time sounded for stone, and I advised that this be done, feeling sure that we would find one. This proved to be the case and I was asked to be present at the operation for its removal. He did an

epicystotomy very neatly and dextrously; there was no hemorrhage. He used the colpeurynter, distending the rectum with about eight ounces of water; there was no trouble with the peritoneum; the stone removed was phosphatic, oval in shape and weighed one ounce two grains. The after treatment differed from the method mentioned by Dr. Roberts: He sutured the bladder; by the way I do not think it is ever possible to select the muscular coat and be absolutely certain that you have not included some portion of the mucous coat. In closing the external wound he left a glass drainage tube in the lower angle for a day, and leaving a permanent catheter inserted for forty-eight hours. The patient did uninterruptedly well. The only difference in technique of the operation between the two was the after treatment. I ask for information and would like to know why Dr. Roberts used the method he spoke of, the open treatment without stitching the bladder.

Dr. W. O. Roberts: I preferred it because the man had cystitis; the principal object in the open treatment was to get rid of the cystitis.

STRICTURE OF THE OESOPHAGUS.

A man twenty-eight years of age, who had typhoid fever in December, was given permission by his physician to eat solid food on the third of February last. He had a chicken cooked but when he made the attempt to eat it, he found that he was unable to swallow. He was brought to me the other day and I believe he has a complete stricture of the oesophagus. I did not use the oesophageal tube to see whether or not it could be passed, but his physician told me a little over four weeks ago he passed a tube into the stomach and the patient then attempted to pass it himself, but it bled so considerably he desisted. I examined him as carefully as I could and could detect no evidence of any tumor or any trouble with the heart or aorta producing pressure upon the oesophagus interfering with deglutition in this way, and had him taken to the infirmary; shortly after going there he began to improve, was able to take milk without any trouble, and I took it that the stricture was due to some local or reflex trouble that would pass away, but for the last three days he has been unable to swallow anything at all and is running down. I would like to know if any Fellow has ever met with a similar case.

DISCUSSION.

Dr. P. Gunterman: I saw a case reported in the *New York Medicinische Monatschrift* where a very similar state of affairs existed after convalescence from typhoid fever; the patient suddenly was unable to swallow. A tumor was detected however causing complete closure of the oesophagus and in a very little while the man died. A post mortem was held revealing a little typhoid fever ulcer in the oesophagus which let fluid enter in between it and the trachea, closing up the oesophagus and trachea. There may have been something of this kind in the case reported by Dr. Roberts.

Dr. P. Gunterman read a paper (see page 806 issue of May 27) on

CHLOROFORM ANÆSTHESIA AND ITS ADMINISTRATION.

DISCUSSION.

Dr. L. S. McMurtry: In the consideration of this important subject one question deserves special attention, viz., Who should administer anæsthetics? Generally speaking, every physician ought to be qualified to administer anæsthetics, and in obstetrical practice anæsthetics are given with impunity and safety without any special skill. When we consider the daily frequency with which anæsthetics are used in skilled and unskilled hands and under all varieties of conditions and complications, it is remarkable that so few accidents occur. But there is something more in administering anæsthetics than procuring respite from pain without the immediate death of the patient. Anæsthetics can do serious damage in surgical cases without producing death. Prolonged and profound saturation with anæsthetics is often the cause of death after surgical operations which are classified as deaths from shock. I do not believe we can too strongly emphasize the responibility of the anæsthetist in surgical work. That is a position of the highest responsibility and requires judgment, care and skill, and since the operator assumes all responsibility it is a position of high trust. The duty of an anæsthetist should be entrusted only to those who have learned how to administer these agents, and who realize the responsibility. In this, as in other

features of surgical work, much of success depends upon attention to details. Fright is of itself an element of danger in anæsthesia. The anæsthetist should be introduced to the patient and establish confidence and give assurance. The operation, however trivial, should not be begun until anæsthesia is produced; by this I mean insensibility to pain. And then a certain degree of anæsthesia should be maintained, using the smallest quantity of the drug possible to attain this condition.

My friend, Dr. Kynett, of Philadelphia, who has had an exceptionally rich experience with anæsthetics, has called attention to a valuable sign of the danger line in anæsthesia: When the addition of fresh ether to the cone fails to produce an up-and-down movement of the wind-pipe the ether should be withdrawn; when that movement occurs, the condition is a safe one.

Dr. J. W. Guest (Visiting): I have listened with a great deal of interest to the paper read, and heartily indorse it in substance. I have found from my personal experience, however, four points in which I would slightly differ with the essayist.

1st. I believe that the stomach should be entirely empty if possible, at the time the anæsthetic is administered. Of course if there be nothing practically in the stomach that much less will the vomiting be.

2nd. In regard to watching the respiration: In giving chloroform about four hundred times, I have had eight accidents or seven accidents and one death; and I have noticed that the circulation and not the respiration was the first to disappear.

3rd. Concerning the cone: I formerly used the towel and paper cone, but in the last one hundred cases I have employed the Esmarch cone and bottle which I think is decidedly the best and safest cone that I have ever seen.

4th. I find that those patients who fear chloroform most usually take it best.

Dr. J. M. Mathews: I suppose I am recognized as a chloroformist, because I believe honestly in the administration of chloroform in preference to ether. I have never had an accident or a failure in administering it; I do not know how often I have given it, but would say between two or three thousand times since I began the practice of medicine. I have administered it four times to-day.

One of the greatest points of interest to be discussed in this matter is, which is the safest anæsthetic of the two? And this is the reason I suggested that we be allowed to mention these points. I believe that if you will take your patients indiscriminately and treat them as physicians usually treat them; that is, without paying attention to the points brought out by Dr. Gunterman, it can be demonstrated that chloroform is the safest anæsthetic. Dr. Gunterman very properly says that the heart should be examined,—he should also have added that the urine should be examined; but who does it?

If you will permit me to say in this connection, it has not been many months since I saw in consultation with one of our most eminent physicians a case in which it was decided to do an operation, and this physician said, for safety we will give him ether. It was understood that he would make an examination of the urine prior to administration of the anæsthetic, but he failed to do so. Reaching the place where the patient was, and having no ether, we decided to give chloroform An analysis of the urine was made afterwards and it was found to contain a very large percentage of albumen. The patient died in less than six months with albuminuria. We gave him chloroform; could we have given him ether safely?

I believe, therefore, if you will take the patients as they come, hospital dispensary and private, recognizing how common diseases of the kidney, etc. are, that we have the safest anæsthetic in chloroform.

Under the first proposition of the essayist, as to who can take chloroform? There is a medico-legal point involved. The law holds the physician responsible for deaths from anæsthesia if he is derelict in his duty, and this is done upon the idea that the physician should make an examination of the patient before he gives the anæsthetic. In other words, it is presumed we know why patients die from anæsthesia. I doubt if we do. Such able physicians as McBurney and McLane have stated that they believed œdema of the lungs caused the death of Col. Shephard. I have heard it hinted at least by physicians here, and there is a doubt expressed even in their own report, whether that was the case or not. The question without a post mortem cannot be settled, whether for instance this man had any

serious kidney trouble, and that was the cause of his death. While it is stated that they made an examination of the urine formerly, from my reading of the case I infer they had not done so recently.

As to who can take chloroform, I must confess that I have given it in heart trouble, where there was organic disease; I have given it where there was organic disease of the kidney; I have given it to exceedingly highly nervous women—and I want to say in this connection that I perfectly agree with Dr. Guest that nervous, hysterical women take chloroform better than anybody else. In other words those who dread the anæsthetic, those of highly sensitive natures go quickly under its influence and have less trouble than any other class of people. I do not believe we can tell by looking at a patient how he is going to take chloroform. It has been my personal observation that fat large men take a less amount of chloroform than small or delicate men. A member of this society will remember a case where a man weighing fully two hundred pounds was thoroughly anæsthetized by one whiff of chloroform, and remained so for twenty or thirty minutes.

As to the signs evidenced that a person is under the effect of the anæsthetic—Bilroth, in his clinic, proposes the method of having the patient count from one to as many as he can, and when he ceases counting, he says he is ready for operation. I have tested this and believe it a good plan. I have seen many cases where the pupil failed to be a good guide. My habit has been, (and I believe it is a good one) to lift the arm and ask the patient to hold it in that position; as long as he does so, or so long as there is an effort made in that direction, he is not ready, but when the arm drops he is ready for the operation. I believe I have never known this to fail.

In regard to stertorous breathing—Dr. Gunterman has very properly said that when this occurs, chloroform should be immediately stopped. He also says any effort at vomiting, an attack of nausea, should be an indication for ceasing the administration of chloroform—if this were done in all cases you would be unable to to operate many times.

As to the method of giving chloroform: I believe it is the concensus of opinion that chloroform should be given rapidly and yet carefully. I dislike very much to have an assistant who seems to be afraid of giving too much cloroform, and gives too little. I am satisfied that deaths do occur in the manner spoken of by Dr. McMurtry, under partial anæsthesia. So thoroughly am I convinced of this that I will not touch the rectum to do a surgical operation until the patient is profoundly under the influence of the anæsthetic; not even to stretch the sphincter muscle. There are many points that might be brought out in this discussion. What we know about chloroform comes more from ones experience and observation. Those that have been in the habit of giving chloroform without accident will prefer it, the same can be said of ether.

Dr. Geo. W. Griffiths: I am in favor of chloroform to the entire exclusion of ether. I have seen chloroform administered at Shiloh, Chickamauga, Stone River, Perryville, in hundreds of cases, all sorts of men with all sorts of injuries, and in all that time—in fact in all my experience extending over a period of more than twenty-five years,—I have never seen but one death and that occurred at the first battle at Green River, in 1861. I do not believe in the use of a cone, I think the chloroform should be used on a napkin and given in this way it lessens the danger as it is by this method that it is better mixed with the atmospheric air.

Dr. T. P. Satterwhite: I prefer chloroform to ether. One of the most objectionable features of ether is the sensation of suffocation. I believe in the administration of chloroform, but think a man ought to administer it very cautiously. I agree with what Dr. Griffiths has said with regard to the admixture of atmospheric air with the chloroform. I differ with Dr. Gunterman in this particular, that in the stage of excitement which we often have in the administration of chloroform, during this period I push the chloroform more vigorously than at any other time. I would like to say with regard to what Dr. McMurtry alluded to, and which I supposed every member of the society knew, the universal custom is that the anæsthetist shall make a charge for his services. I would not think of asking a man to administer an anæsthetic without expecting him to make a charge.

In nine-tenths of the surgical operations the anæsthetist has the most responsible position.

Dr. I. N. Bloom: It is largely a question of locality as to the preference for ether or chloroform. In Boston, and with those people who have gone there to complete their medical education, ether is used almost exclusively. In the south and west for some years chloroform has been employed universally. I think anyone who reads the journals will see the tendency toward returning to ether; an increase of ether advocates. In New York it is about evenly divided and apparently remains in *statu quo*. It is claimed—I received my education in Boston—that the mortality in a given number of cases, say in possibly 100,000 cases, was less from ether than from chloroform. I know that this is the principal reason why ether is advocated by those who teach the use of anæsthetics in surgery in Harvard College. Now I also know that there is no strong advocate of chloroform who does not maintain that the mortality is less from chloroform. I do not think any of us here are competent to judge. I think there is only one way of demonstrating this and that is to take the first 100,000 cases or even a greater number of cases and following up the mortality, and even then it is not satisfactory. A man may have a death from imperfect knowledge of the method of administering, or as has been suggested very properly by Dr. Mc Murtry, by incomplete anæsthesia. I do not think any discussion among a few men will convince either side as to which is the better anæsthetic to use, and I believe it is like the discussion of a political question "when it is finished you are unchanged in your opinion."

Dr. P. Gunterman: I simply wish to remark that in my paper thus far nothing whatever was said with reference to ether, although the discussion seems to have branched off in that direction.

CORRESPONDENCE.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

Editor Medical and Surgical Reporter:—I beg to inform you, and your readers and exchanges through you, that there in *no foundation* in the rumors referring to a postponement of the Eleventh International Medical Congress, such is the information conveyed to me in a letter of the Secretary General's dated Genoa, May 15th.

It is officially announced, that part of the 15th Section of the Congress will be dedicated to the exclusive consideration of Cholera and Quarantine. Professors Cunningham and Koch are expected to participate in the proceedings of this Subsection.

Beside the North German Lloyd, the Hamburg American Packet Co. and the Campagnie Générále Transatlantique—the Netherland-American Steam Navigation Company (39 Broadway N. Y.) offers reduced rates to visitors of the Congress. The Hamburg American Packet Co. writes to say that the families of members are entitled to all the reductions.

Very respectfully yours

A. Jacobi.

New York, May 28, 1893.

A clergyman, one hot Sunday, observing a deacon asleep in church, called out: "Brother Austin, please open the window a little. Physicians say it is unhealthy to sleep in a hot room."—*Quincy Journal.*

Small Boy—"Papa, what are roosters?"

Father—"Gentlemen hens, my son."

Small Boy—"Do they lay eggs or hatch chickens?"

Father—"No."

Small Boy (meditatively)—"Only hens and ladies hatch chickens and children, consequently I won't have the anxiety of hatching children."—*Ex.*

THE MEDICAL AND SURGICAL REPORTER

ISSUED EVERY SATURDAY

ADDRESS
Care P. O. Box 843, Philadelphia.

HAROLD H. KYNETT, A. M., M. D.,
Editor.

RODERIC C. PENFIELD,
Publisher.

316 = 18 = 20 North Broad Street,
PHILADELPHIA.

TERMS:—Five Dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable only to the Publisher, and when in sums of Five Dollars or less, should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS:—We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

SATURDAY, JUNE 3RD, 1893.

EDITORIAL.

FUROR—OPERANDI AND MODERN LISTERIANISM.

Probably in the whole realm of Medical Science, from its early origin to the present time, there never was a doctrine sprung on the profession, so to speak, which was so generally and eagerly accepted by the whole civilized world; which became so popular, and finally was regarded as a fixed dogma, that has been so short-lived as the *antiseptic* theory. To-day it must be admitted that orthodox antiseptic treatment is chiefly interesting only from an historical standpoint for it has, in recent times, been by many of our most respected authorities as fiercely condemned as it was in but the near past supported and recommended.

In Mr. Joseph Lister's address on Antiseptics, at the Queen's College Hospital, delivered on the 18th of January, 1893, it is only too apparent that he has found it necessary to turn his back on the offspring which, but a few short years ago, he gave to the world, and which was regarded as a boon of priceless value. But in this address the spray is not mentioned and Bichloride of Mercury is declared an unreliable agent.

Chiene, in his address to the British Medical Association in 1891, declared that every sort of chemical solution was a foreign substance in a healthy wound. Gynecologists in a body cast aside antiseptics as useless and dangerous in the surgery of the peritoneum. The enormous stone or glass jars, the irrigating hose and the operator's wooden clogs to lift him out of the pools of irrigating fluids, these former indispensible appurtenances of the ideal operating room, have one and all been thrown out.

Manley, of New York, has called attention to the destructive irritation which he noticed when the corrosive solution was employed in cranial surgery, and reported a number of amputations in which, though primary union followed, useless stumps resulted, osteo-myelitis followed and consecutive amputation was required.

Antiseptics enormously increased the number of surgical operations for a time, so that for a while it seemed that the field of medicinal constitutional treatment would be greatly narrowed. We had a veritable *furor-operandi*. But it has swept over and now that the reaction has set in, we may ask "if these new theories have not led to too much mutilation, and if as good or even better results might not have succeeded by tentative measures combined with an appropriate dietary, internal medication and more time."

Antiseptics have their place, but let us distinctly understand their powers and properties before we employ them, for without question their indiscriminate employment in the past has in many cases worked incalculable injury.

THE NEW MEDICAL LAW IN PENNSYLVANIA.

AN ACT

To establish a Medical Council and three State Boards of Medical Examiners; to define the powers and duties of said Medical Council and said State Boards of Medical Examiners; to provide for the examination and licensing of practitioners of medicine and surgery; to further regulate the practice of medicine and surgery, and to make an appropriation to the Medical Council.

Whereas, the safety of the public is endangered by incompetent physicians and surgeons, and due regard for public health and the preservation of human life demands that none but competent and properly qualified physicians and surgeons shall be allowed to practice their profession.

SECTION 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met and it is hereby enacted by the authority of the same. That there shall be established a Medical Council of Pennsylvania, consisting of the Lieutenant Governor, the Attorney General, the Secretary of Internal Affairs, the Superintendent of Public Instruction, and the President of the State Board of Health, and Vital Statistics and the Presidents of the three State Boards of Medical Examiners provided for in this act.

SECTION 2. The said council shall be known by the name and style of the Medical Council of Pennsylvania and may make and adopt all necessary rules and regulations and by-laws not inconsistent with the constitution and laws of this Commonwealth, or of the United States and shall have power to locate and maintain an office within this State for the transaction of business. Five members of the said council shall constitute a quorum for the transaction of business.

SECTION 3. The said council shall organize at Harrisburg within ten days from the date of the organization of three boards of medical examiners and shall elect from its own number a president and a secretary who shall also act as treasurer, both of whom shall hold their offices for one year or until their successors are chosen.

SECTION 4. The members of the said council shall receive no salary, except the secretary and treasurer, who shall receive a salary of not over five hundred dollars and who shall file with the president of the council a bond in the sum of one thousand dollars condition for the faithful performance of his duties. The necessary expenses of the said council shall be paid out of the appropriation made in section sixteen of this act and any balance remaining from the appropriation after the disbursements herein specified shall be paid into the Treasury of the Commonwealth.

SECTION 5. The said medical council shall hold two stated meetings in each year at Harrisburg and may hold special meetings at such times and places as it may deem proper. It shall supervise the examinations conducted by the three State Boards of Medical Examiners of all applicants for license to practice medicine and surgery in this Commonwealth and shall issue licenses to practice medicine and surgery to such applicants as have presented satisfactory and properly certified copies of licenses from State Boards of Medical Examiners or State Boards of Health of other States as provided for in section thirteen of this act, or as have successfully passed the examination of one of the three State Boards of Medical Examiners, but all such examinations shall be made by the State Boards of Medical Examiners established in section six of this act. And the said medical council shall have no power, duty, or function except such powers, duties, and functions as pertain to the supervision of the examinations of applicants for licenses to practice medicine and surgery and to the issuing of licenses to such applicants as have successfully passed the examination of one of the State Boards of Medical Examiners, or have presented satisfactory and properly certified copies of licenses from State Boards of Medical Examiners or State Boards of Health of other States as provided for in section thirteen of this act.

SECTION 6. It is further enacted that from and after the first day of March, Anno Domini one thousand eight hundred and ninety-four, there shall be and continue to be three separate boards of medical examiners

for the State of Pennsylvania, one representing the medical society of the State of Pennsylvania, one representing the homœopathic medical society of the State of Pennsylvania, one representing the eclectic medical society of the State of Pennsylvania.

Each board shall consist of seven members and each of said members shall serve a term of three years from the first day of March next after his appointment with the exception of those first appointed who shall serve as follows, namely: Two of each board for one year, two of each board for two years, and three of each board for three years, from the first day of March, Anno Domini one thousand eight hundred and ninety-four.

The Governor shall appoint the members of said boards of examiners respectively from the full lists of the members of the said medical societies, which shall on or before the first day of January, one thousand eight hundred and ninety-four, and annually thereafter, be transmitted to the Governor under the seal and signed by the secretary of the society so nominating. From these lists of nominees respectively the Governor shall during the month of January, Anni Domini one thousand eight hundred and ninety-four, appoint three separate boards of medical examiners, each board to be composed exclusively of members of the same medical society. In case of failure of any or all said medical societies to submit lists as aforesaid the Governor shall appoint members in good standing of the corresponding society or societies entitled to nominate without other restriction. Each one of the said appointed must be a registered physician, in good standing and shall have practiced medicine or surgery under the laws of this State for a period of not less than ten years prior to such appointment.

The Governor shall fill vacancies by death or otherwise for unexpired terms of said examiners from the respective lists submitted by the said medical societies and may remove any member of any said boards for continued neglect of the duties required by this act or on recommendation of the medical society of which said members may be in affiliation, for unprofessional or dishonorable conduct.

The Governor shall in his first appointments designate the number of years for which each appointee shall serve. The appointments of successors to those numbers whose term of office will expire on the first day of March, of each year, shall be made by the Governor during the month of January of such year upon the same conditions and requirements as hereinbefore specified, with reference to the appointment of three separate examining boards, each to be composed exclusively of members of the same medical school and society as hereinbefore provided.

Section 7. Said boards shall be known by the name and style of Boards of Medical Examiners of the State of Pennsylvania. Every person who shall be appointed to serve on either of said boards shall receive a certificate of appointment from the Secretary of the Commonwealth.

Each of said boards shall be authorized to take testimony concerning all matters within its jurisdiction and the presiding officer, for the time being, of either of said boards, or of any of the committees thereof may issue subpœnas and administer oaths to witnesses. Each of said boards of examiners shall make and adopt all necessary rules, regulations and by-laws not inconsistent with the constitution and laws of this State, or of the United States, whereby to perform the duties and transact the business required under the provisions of this act, said rules, regulations and by-laws to be subject to the approval of the Medical Council of Pennsylvania established by this act.

Section. 8. From the fees provided by this act the respective boards may pay, not to exceed said income, all proper expenses incurred by its provisions and if any surplus above said expenses shall remain at the end of any year it shall be apportioned among said examiners pro rata according to the number of candidates examined by each, *Provided,* That the Medical Council shall keep separate accounts of all fees received from physicians applying for licenses to practice medicine and surgery and shall not devote any such fees to the uses of the council or to the uses or remuneration of any other examining board than that of the society with which the physician who pays the fee wishes to be affiliated.

Section 9. The first meeting of each of the examining boards respectively shall be held on the first Tuesday of April, one thousand eight hundred and ninety-four, suitable notice in the usual form being given with the notice of their appointment by the Secretary of the Commonwealth to each of the members thereof, specifying the time and place of meeting.

At the first meeting of each of the boards respectively an organization shall be effected by the election from their own membership of a president and secretary. For the purpose of examining applicants for license each of said boards of medical examiners shall hold two or more stated or special meetings in each year, due notice of which shall be made public at such times and places as they may determine. At said stated or special meetings a majority of the members of the board shall constitute a quorum thereof but the examination may be conducted by a committee of one or more members of the board of examiners duly authorized by said boards.

Section 10. The several boards of medical examiners shall, not less than one week prior to each examination submit to the Medical Council of Pennsylvania questions for thorough examinations in anatamy, physiology, hygiene, chemistry, surgery, obstetrics, pathology, diagnosis, therapeutics, practice of medicine and materia medica. From the lists of questions so submitted the council shall select the questions for each examination and such questions for each examination shall be the same for all candidates except that in the departments of therapeutics, practice of medicine and materia medica the questions shall be in harmony with the teachings of the school selected by the candidate.

Section 11. Said examinations shall be conducted in writing in accordance with the rules and regulations prescribed by the Medical Council of Pennsylvania and shall embrace the subjects named in section ten of

this act. After each such examination the board having charge thereof, shall without unnecessary delay act upon the same. An official report of such action signed by the president, secretary and each acting member of said board of medical examiners stating the examination average of each candidate in each branch, the general average and the result of the examination, whether successful or unsuccessful, shall be transmitted to the Medical Council. Said report shall embrace all the examination papers, questions and anwers thereto. All such examination papers shall be kept for reference and inspection for a period of not less than five years.

SECTION 12. On receiving from any of said boards of medical examiners such official report of the examination of any applicant for license the Medical Council shall issue forwith to each applicant who shall have been returned as having successfully passed said examination and who shall have been adjudged by the Medical Council to be duly qualified for the practice of medicine, a license to practice medicine and surgery in the State of Pennsylvania. The Medical Council shall require the same standard of qualifications from all candidates except in the departments of therapeutics, practice *of medicine* and materia medica, in which the standard shall be determined by each of the boards respectively. Every license to practice medicine and surgery issued pursuant to this act shall be subscribed by the officers of the Medical Council and by each medical examiner who reported the licentiate as having successfully passed said examinations. It shall also have affixed to it, by the person authorized to affix the same, the seal of this Commonwealth.

Before said license shall be issued it shall be recorded in a book to be kept in the office of the Medical Council and the number of the book and page therein containing said recorded copy shall be noted upon the face of said license. Said records shall be open to public inspection under proper restrictions as to their safe keeping and in all legal proceedings shall have the same weight as evidence that is given to the conveyance of land.

SECTION 13. From and after the first day of July, Anno Domini one thousand eight hundred and ninety-four, any person not theretofore authorized to practice medicine and surgery in this State and desiring to enter upon such practice may deliver to the Secretary of the Medical Council, upon the payment of *a fee of twenty-five* dollars, a written application for license, together with satisfactory proof that the applicant is more than twenty-one years of age, is of good moral character, has obtained a competent common school education and has received a diploma conferring the degree of medicine from some legally incorporated medical college of the United States, or a diploma or license conferring the full right to practice all the branches of medicine and surgery in some foreign country. Applicants who shall have received their degree in medicine after the first day of July, one thousand eight hundred and ninety-four, must have pursued the study of medicine at least *three* years including three regular courses of lectures in different years in some legally incorporated medical college or colleges prior to the granting of said diploma or foreign license, *and after the first day of July, eighteen hundred and ninety-five, such applicants must have pursued the study of medicine for at least four years, including three regular courses of lectures in different years in some legally incorporated medical college or colleges prior to the granting of said diploma or foreign license.* Such proof shall be made, if required, upon affidavit. Upon the making of said payment and proof the Medical Council, if satisfied with the same, shall issue to said applicant an order for examination before such one of the State Boards of Medical Examiners as the applicant for license may select. In case of failure at any such examination the candidate after the expiration of six months and within two years shall have the privilege of a second examination by the same board to which application was first made without the payment of an additional fee. And it is further provided, that applicants examined and licensed by State Boards of Medical Examiners or State Boards of Health or other States, on payment of a fee of fifteen dollars to the Medical Council and on filing in the office of the Medical Council a copy of said license certified by the affidavit of the president or secretary of such Board, showing also that the standard of acquirements adopted by said State Board of Medical Examiners, or State Board of Health, is substantially the same as is provided by sections eleven, twelve and thirteen of this act, shall without further examination receive a license conferring on the holder thereof all the rights and privileges provided by sections fourteen and fifteen of this act.

SECTION 14. From and after the first day of March, Anno Domini., one thousand eight hundred and ninety-four, no person shall enter upon the practice of medicine or surgery in the State of Pennsylvania unless he or she has complied with the provisions of this act and shall have exhibited to Prothonotory of the court of common pleas of the county in which he or she desires to practice medicine or surgery a license duly granted to him or her as hereinbefore provided whereupon he or she shall be entitled upon the payment of one dollar to be duly registered in the office of the Prothonotary of the court of common pleas in the said county and any person violating any of the provisions of this act shall be guilty of a misdemeanor and upon conviction thereof in the court of quarter sessions of the county wherein the offense shall have been committed shall pay a fine of not more than five hundred dollars for each offence.

SECTION 15. Nothing in this act shall be construed to interfere with or punish commissioned medical officers serving in the army or navy of the United States or in the United States Marine Hospital service while so commissioned or medical examiners of relief departments of railroad companies while so employed or any one while actually serving as a member of the resident medical staff of any legally incorporated hospital, or any legally qualified and registered dentist exclusively engaged in the practice of dentistry, or shall it interfere with or prevent the dispensing and sales of medicines or medical appliances by apothecaries, pharmacists, or

interfere with the manufacture of artificial eyes, limbs or orthopedical instruments or trusses of any kind, for fitting such instruments on persons in need thereof, or any lawfully qualified physicians and surgeons residing in other States or countries meeting registered physicians of this State in consultation, or any physician or surgeon residing on the border of a neighboring State and duly authorized under the laws thereof to practice medicine and surgery therein whose practice extends into the limits of this State; Provided, that such practitioner shall not open an office or appoint a place to meet patients or receive calls within the limits of Pennsylvania or physicians duly registered in one county of this State called to attend cases in another county but not residing or opening an office therein. And nothing in this act shall be construed to prohibit the practice of medicine and surgery within this Commonwealth by any practitioner who shall have been duly registered before the first day of March, Anno Domini one thousand eight hundred and ninety-four, according to the terms of the act entitled "An act to provide for the registration of all practitioners of medicine and surgery" approved the eighth day of June, Anno Domini one thousand eight hundred and eighty-one, and one such registry shall be sufficient warrant to practice medicine and surgery in any county in this Commonwealth.

SECTION 16. The sum of two thousand dollars is hereby appropriated out of any moneys in the State Treasury not otherwise appropriated, for the salary of the secretary and treasurer of said medical council and the necessary expenses of said council; one thousand dollars thereof for the year beginning January, one thousand eight hundred and ninety-four, and one thousand dollars thereof for the year beginning January, one thousand eight hundred and ninety-five.

SECTION 17. All acts or parts of acts of Assembly inconsistent herewith shall be and are hereby repealed.

TRANSLATIONS.

REPORT OF THE "MAISON D'ACCOUCHEMENTS BAUDELOQUE," UNDER THE MANAGEMENT OF PROF. A. PINARD AND REPORTED BY DR. G. LEPAGE.*

This report containing an exhaustive study of all the possible phases of pregnancy, labor, delivery and subsequent complications presented in both a tabular and descriptive form, will be of interest to the obstetrician, those particular cases which occur less often in every day practice, may seem of interest given in the abstract.

One is an abdominal section done for extra-uterine pregnancy of seven months in a primipara, æt. 28, married two years. Had always menstruated regularly until July 9th, when there was an omission, but in the latter part of August it returned; this ceased after a few days and was soon followed by abdominal pains extending to the lumbar region and small pelvis, necessitating the recumbent position. Morphia was administered but the symptoms continued for fifteen days after this slight improvement until October, when the same train of symptoms recurred and again diminished until November.

At this time she expelled portions of membrane with but slight bleeding or pain. A consultation resulted in making a diagnosis of a retroverted pregnant uterus. Extra-uterine pregnancy was considered and dismissed.

Hot antiseptic injections and absolute rest were ordered. Toward the middle of December all painful symptoms disappeared.

The patient, though able to be up, tires very easily, her abdomen increasing in left lateral half, where a round tumor can be felt reaching to the level of the umbilicus. Not much general emaciation but great general weakness.

During February, motion was felt for the first time, which ceased after the third week.

The patient was admitted on the 20th of March; the tumor easily outlined, is immovable, about the size of a four months pregnant uterus, is tender to touch, and some fluctuation, but no motion can be detected; a mass below and to the right is found to be the uterus. The operation—April 1st, 1892—Median incision, the cyst is sutured to the abdominal wall, removal of dead fetus—290 gm. The placenta is left, the cavity cleansed with antiseptics and packed with iodoform gauze. April 30th the last of the

*Translated for THE MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

placenta was removed. The patient was discharged May 29th.

One case of Ischio-pubiotomy after the method of Farabœuf, performed January 10th, 1893.

Patient æt. 32; previous pregnancies:

1st.—May, 1887; oblique flat pelvis; obliquity to the right; version; forceps; Basiotripsy.

2nd.—May, 1888; version; difficult extraction of the head; child resuscitated with difficulty; lived five months.

3rd.—May, 1890; midwife ruptured membranes. First doctor applied forceps five times. Second doctor applied once, also without effect. The author practiced version and delivered the body, but the head could not be extracted, and craniotomy remained unsuccessful; not until the combined force of three was used could the head be delivered.

4th.—September, 1891; induced premature labor, forceps, prolapse of the cord, child born dead.

5th.—September, 1892; on consultation with M. Farabœuf it was deemed best to wait full term and then perform Ischio-pubiotomy.

Labor set in November 8th; afternoon; 9 A. M. November 9th the operation was performed. The Ischio-pubic articulation of the right side was divided by a chain saw—the child extracted with the aid of Farrier's forceps. The only sutures taken were those in the soft parts, the bone being readily placed in proper contact. The patient was treated same as those for symphysiotomy. December 19th, able to walk without difficulty; child weighed then nearly eleven pounds. There were thirteen symphysiotomies. Three children died after birth. One died the next day owing to an injury of the parietal portion of the cranium. The second died of cyanosis on the third day. The third died on day of birth, cause unknown.

The patients seem all to have recovered fully and are able to walk comfortably.

The following tables will give a more definite account of all the cases and their results, reported.

Resume of the statistics of the clinic of Bandelocque from January 1st, 1890, to January 1st, 1893.

Fiessinger draws the following conclusions:

1. There exists a form of scarlatina in which the fever may be entirely absent (below 38° by the rectum) or in which it may assume a number but slightly elevated, and that in an essentially transitory manner (by the rectum 38° to 38½°).

2. This form of scarlatina is observed in the same epidemic and alongside of the grave and pyretic forms; it is contagious and may give rise to the ordinary scarlatina complicated with Bright's disease, or with a pseudo-membranous angina.

3. There is no local sign to differentiate the apyretic from the ordinary scarlatina; the angina, the eruption, the desquamation are the same in their aspect and duration; the state of the tongue is, on the contrary, a little modified; we have not observed the raspberry tongue bristling with papillæ so peculiar to the ordinary scarlatina.

4. The pulse is not always accelerated in the apyretic scarlatina.

5. That which characterizes the apyretic scarlatina is the absence of general phenomena. Save the nights which are at times broken, the patients do not seem to suffer and are happy.

6. The diagnosis from certain scarlatinoid erythemata is very difficult; it is a question whether the same germ, infectious in different degrees of virulence, does not produce both these erythemata and the classical scarlatina.

ABSTRACTS.

THE REMOVAL OF THE GRAVID UTERUS BY ABDOMINAL SECTION.

Dr. More Madden, having in a former volume of the Transactions of the Royal Academy of Medicine in Ireland, reported a case in which he had been obliged to remove the gravid uterus, now in the present communication submitted the notes of a recent case of the same kind, together with some general observations on such operations.

In the last case referred to, in which he was compelled to perform a Porro-Müller's operation, the patient was a woman aged thirty-two, two months pregnant, and of well-marked carcinomatous cachexia, suffering from a fast-growing uterine tumour, which, from the intense suffering it occasioned, the rapidity of growth (it having so developed from the time it was first recognized, only three months previously, so as to fill the abdominal cavity, and cause such dyspnœa as to prevent her sleeping save in a sitting position) as well as from the extreme emaciation and characteristic cachexia, was diagnosed as probably malignant. The symptoms being most urgent, and the patient being apparently *in extremis*, it was decided as a forlorn hope to give her whatever chance the amputation of the uterus might afford. From the time of her being brought into the hospital until she was placed on the operation table the patient was in a condition of extreme prostration from loss of rest, continual pain, and inability to take food, and was apparently kept alive by the free administration of stimulants. In that operation, which was performed on April 10th, 1893, he had the assistance of his colleagues, Drs. Leutaigue and Coppinger, and Dr. A. Smith, of St. Vincent's Hospital. The enormous tumour here shown, growing from the fundus was partially gangrenous, and owing to extensive adhesions there was considerable difficulty in its removal and in the ligation of the ligaments. The operation was, therefore, necessarily prolonged; and though she recovered from the immediate shock, and for a couple of days gave hope of recovery, she was then attacked by peritonitis, and sank rapidly.

The excision by abdominal section of the gravid uterus, which is generally known by the name of the operator, Professor Porro, of Pavia, by whom it was first successfully accomplished in 1879, though previously performed by Dr. Storer, of Boston, was originally designed as an obstetric operation in lieu of the Cæsarean section. It has been subsequently considerably modified and im-

proved by Fruend, of Breslau, and Müller, of Berne, to whose operation, with several further modifications, More Madden has resorted to in three cases of pregnancy complicated by urgent symptoms arising from malignant, or supposed malignant, disease of the fundus or body of the uterus.

The mortality of Porro's operation under the most favorable circumstances, that is, in obstetrics where the condition of the uterus is presumably a normal one, has been 56 per cent.; hence the results in these three cases of removal of uterus for such disease as existed in all these cases—namely, two deaths, and one recovery, being a mortality rate of 66.6 per cent., considerably less than that of Freund's operation—are by no means exceptionally unfavourable when we consider the circumstances of thes cases and the condition of the patients so operated on, as the last possible chance of relieving suffering and prolonging life in cases apparently otherwise beyond hope. At the same time More Madden thinks it only justifiable to perf m such operations, as was the case in the three instances above referred to, as a *dernier ressort*, in compliance, and with the entreaty of a patient fully aware of all the risk of the procedure and beyond other methods of relief.

Finally, in this connection, it may be added, that in obstetric practice, for which primarily designed as a substitute for Cæsarean section, there can be no ground now-a-days for recourse to either Porro's operation, or any of its subsequent modifications. Within the last few years, owing mainly to the improvements effected by Professor Sanger, of Leipsic, and also, and above all others, by Professor Murdoch Cameron, of Glasgow, the Cæsarean section (More Madden's first case of which was reported in "The Dublin Practice of Midwifery," published twenty-one years ago) has been robbed of its former terrors. No triumph of modern abdominal surgery has probably been equal to that which has taken place in the accomplishment of this operation by the method of Cameron, by whom the Cæsarean section has been performed in twenty cases with only two deaths, being a mortality hardly greater than that generally obtained in ordinary ovariotomy. With that method thus available, and with the exceptional experience of Cameron to guide us, it is, Dr. More Madden thinks, therefore evident that we would no longer be justified in obstetric practice in resorting, whether by Müller-Porro or any other method, to an operation so terribly fatal as the removal of the gravid uterus has always proved and must always remain.

Dr. Lane would like to know could Dr. More Madden assign any cause for this rapid growth in what would appear to be a monster fibroma.

Dr. Tweedy asked if he had any reason to believe that the disease was confined to the uterus, and had not spread to the surrounding tissues. He did not see the necessity for washing out the abdominal cavity if nothing had got into it. If the blood has ceased, and if the clots have been taken away and asepsis assured, he did not see the use of a drainage-tube; it often ended in a fæcal fistula.

The President said that Dr. More Madden appeared to think, from the constitutional symptoms present, that it was a case of malignancy. But then the woman was only thirty-three years of age, and there was no matting of the tissues, no disease of the cervix uteri. Another remarkable coincidence was the absence of ascites. The late Dr. Stokes always laid down that in such cases ascites was a sign of malignancy. The difficulty, to his mind, was how to account for the sloughing of the tumour. He thought that they must bow to the pathologists and agree with them that it was a large fibroid of the uterus. With regard to the choice of operation, he would be more inclined to the ideal operation—*i. e.*, removal of the uterus complete. He did not see the advantage of the drainage-tube.

Dr. More Madden, in reply to Dr. Lane as to the nature of the tumour, he (Dr. Madden) bowed entirely to the decision of the pathologist to the hospital, Dr. M'Weeney, but, at the same time, he ventured to think that before abdominal section any man might be justified, from all the symptoms—the extremely rapid growth, the constitutional cachexia and incessant local pain—in diagnosing it as malignant. As to washing out the peritoneal cavity, he must say that when the operator's hands, and possibly the hands of the assistant, have been introduced into the peritoneal cavity, he very much preferred washing out the cavity, because no amount of wasing of hands can possibly

prevent the risk of septic infection. He was not aware of any means of sterilizing the atmosphere in the operating room, and therefore he thought washing out a wise precaution, and he would always continue to do it. He did not like the drainage-tube much, but in a large operation such as this one, and where there was the slightest danger of septic contamination, he thought they could not take too many precautions. They could also, if that should subsequently become necessary, wash out the peritoneal cavity through the tube.

SOME OTOLOGICAL DON'TS.

That the ear is more sinned against by acts of commission than of omission in the treatment of its diseases, says Dr. Chas. M. Shields, is a statement that will be agreed to by most specialists, and may serve as an excuse for the negative title of these remarks.

Firstly. *Don't syringe the ear except for a purpose.* That is, do not use the syringe on general principles with every patient that complains of his ear, but restrict the use of the instrument to its legitimate purpose of removing extraneous matter such as foreign bodies, wax, pus, etc.

It is too often the case that patients are directed to syringe their ears because it is easier to give such advice than to make a diagnosis. Warm water is not a panacea for all diseases of the ear, and it is as important to make a diagnosis here before applying remedies as it is in the treatment of other organs.

Should the family physician not always have an ear speculum and mirror with him, a truncated cone of stiff paper will answer for one and an ordinary hand-glass for the other. With their aid, and, after the auditory canal has been cleansed by the proper use of warm water, it can be determined whether the syringing can appropriately be continued for the removal of products of suppuration, or as the medium of conveying antiseptic agents to the parts, or for the poultice-like effect of the hot water; or whether its continuance would not rather do the harm that not infrequently results from its softening and soddening effect upon the drum and other tissues. Eczema, for which the auditory canal is such a favorite site, is confessedly made worse by the application of moisture, and yet I suppose that out of every twenty such cases that I see, syringing has been suggested in nineteen of them. In long-continued inflammations of the walls of the auditory canal and the drum, unless there are discharges to be removed, the constant use of water soddens the tissues and makes them an easier prey to inflammatory processes.

Secondly. *Don't use instruments to remove foreign bodies from the ear until the syringe has failed.* The ingenuity that has been displayed in inventing instruments for the removal of foreign bodies from the ear is worthy of a better cause. A well-directed stream of warm water will accomplish the desired result in the vast majority of cases.

Not with the so-called ear-syringe, however, that is commonly sold in the drug stores, that has its end rounded into a bulbous extremity, which effectually prevents your directing the stream to any particular place; but with an instrument that will hold at least four ounces and that has a long tapering nozzle which will permit you to throw the water along the wall of the auditory canal which permits its easiest flow behind the foreign body.

Some of the suggested appliances have been of the gimlet order, and, while being screwed into the foreign body, pushes it through the drum. A form of lever in the hands of an experienced person is often an effective and safe instrument, but if carelessly used may do great damage to the walls of the canal. While slender forceps are useful when the object to be removed is not large, they are useless when most wanted because of the lack of space for their introduction between the foreign body and walls of the canal. Where the syringe fails, perhaps the most satisfactory and safe instrument is a loop of silver wire gently insinuated around the foreign body.

Thirdly. *Don't consider and speak of all pain in the ear as a neuralgic earache.* Are not physicians largely responsible for

the laity considering inflammatory pain in the ear as a neuralgic earache? Ninety-nine per cent of our patients so describe it. As we all know, the fact is that nearly all pain in the ear means *inflammation* there—acute, catarrhal, or purulent inflammation of the middle ear that may rupture the drum, impair hearing, or extending into the mastoid, result fatally. Or else inflammatory processes in the auditory canal that, while not serious in their results, are usually attended by several days of acute discomfort.

Pain in the ear is rarely neuralgic in character, and is no more properly described as *ear-ache* than would be gastritis as gastralgia or peritonitis as belly-ache. This misnomer often lulls the patient into a false sense of security that is only dissipated when he discovers that he has a resulting ruptured drum, and that his hearing is permanently impaired.

Fourthly. *Don't prescribe sweet oil for pain in the ear.* In the first place, it does no good. The sense of comfort which may follow the use of any warm liquid poured in the ear may be obtained just as well by a harmless one.

Sweet oil or any vegetable or animal oil may undergo decomposition and make favorable soil for the growth of aspergillus or other vegetable fungi which may be most destructive to the organ. Then it gums up the canal and interferes with examination subsequently.

Fifthly. *Don't lose sight of the fact that the auditory canal and external surface of tympanum is not an absorbing surface.* If you do, you will often be disappointed in the effect of agents prescribed to be dropped in the ear. The lining of these parts being a continuation of the skin does not possess the absorbing properties of mucous membranes, and agents are sparingly, if at all, taken up. If there bf an exception it is with the combination oe atropia and cocaine—one grain of the former and six of the latter in two drachms of water. This should not be used, of course, where a perforation of the drum is known to exist or where an otorrhœa would suggest a perforation, as an excessive quantity might find its way to the throat through the eustachian tube. Six or eight drops of this solution instilled warm into the ear often relieves pain to a marked degree. As a rule, however, absorption of remedies in the auditory canal is so limited as to make their use very unsatisfactory.

Sixthly. *Don't tell your patient that it is dangerous to stop an otorrhœa.* This injunction would seem an unnecessary one were it not for the fact that scarcely a day passes that some patient does not give as an excuse for the neglect of an otorrhœa of years' duration that his doctor told him it would be dangerous to stop it. As well consider it dangerous to stop a gonorrhœal flow or a leucorrhœal discharge!

Purulent discharge from the middle ear means the continuance of inflammatory action there with the resulting damage to the parts and the added danger of extension into the mastoid process.

To neglect to treat the cause of an otorrhœa is not only to sacrifice the sense of hearing without an effort, but in endangering life, as is evidenced by the refusal of life insurance companies to accept as risks individuals having a chronic discharge from the ear.—*Practice.*

THE TREATMENT OF GANGRENOUS INTESTINE.

In a certain proportion of cases of strangulated hernia the bowel is found in a gangrenous condition, and the treatment of such cases in the past has practically been limited to relieving the constriction and to the creation of an artificial anus. The mortality under these circumstances is very considerable, in fact, the discovery of gangrenous intestine has hitherto been looked upon as an indication of the hopeless nature of the case. Judging from a paper read by Dr. Kendal Franks before the Medical and Chirurgical Society, these cases are not as hopeless as statistics would lead one to infer. He urges with some show of reason, basing his conclusions on a tolerably extensive array of statistics, that resection of the gangrenous gut with immediate suture affords the patient a much better chance of recovery. Nor was this conclusion seriously questioned by the experienced surgeons who

had assembled to hear what the author had to say on behalf of a procedure that certainly strikes one as severe, considering the usually very depressed condition of such patients. The discussion turned mainly on the question as to whether the operation should be completed on the site of the original wound made for the relief of the femoral or inguinal hernia, or whether, after the preliminary palliative measures, it should be performed through a median abdominal incision made for the express purpose. Opinion on the whole was in favour of the resort to abdominal incision, and this is probably the view that will commend itself to most unprejudiced surgeons. It is evident that the thoroughness of the examination of the gut and the freedom of manipulation could never be the same through such a small aperture as that afforded by the inguinal or the crural canal, apertures, moreover, which cannot be safely enlarged. By this procedure the mortality has been reduced from something like 95 to about 56 per cent., a brilliant enough achievement considering the very unfavourable circumstances under which it is necessarily undertaken. One point that came out very clearly in the discussion was the impunity with which relatively considerable lengths of gut can be removed. One case was mentioned in which over a yard had been removed, and this without interfering with the recovery of the patient. It is indeed all important to remove every inch of damaged tissue, otherwise no suture, however perfect, can be relied upon to hold. A very large proportion of the failures after enterectomy are attributable to non-compliance with this salutary rule, and it cannot be too strongly impressed on surgeons that the kind of suture is of far less importance than the fact of its being applied to healthy tissue. There must, of course, always be cases which come under treatment at such a late period that nothing can be done. These "too late" cases are the operator's horror, for they weigh down on the statistics with an unduly large proportion of fatalities, although death has really nothing to do with the operation *per se*. Dr. Franks has called attention to a means of rescuing a certain proportion of patients otherwise condemned to inevitable death, and he has succeeded in divesting gangrenous intestine of half its terror.—*Med. Press and Circul.*

NEURALGIA.

Dujardin-Beaumetz writes: A most interesting study, even from a practical or therapeutical standpoint, is that of the true seat of neuralgic pain. The entire subject can be reduced to a single question. Is the pain of the different forms of neuralgia really originated at the very spots at which the patients complain of it, or is it simply felt at those spots as though it arose there, in the same way, for instance, as patients who have undergone amputation of a limb, still complain of pain in the stump although the limb, which was the seat and sole cause of their suffering, has been removed?

The former hypothesis seems probable *a priori*, and has given rise to the so-called peripheral theory of neuralgia; but a number of neuropathologists, and among them some very eminent men, defend what is known as the central theory of such suffering. Although there can be no doubt that the latter theory is not applicable to all cases, still it accounts for the greater number of them, and is based on arguments that are well fitted to carry conviction, and of which the principal ones are the following:

When the nerve has been completely severed, as is sometimes done in cases of neuralgia that defy all treatment, it is not uncommon to find the pain going on unchanged after the operation; it could not, therefore, have had a peripheral origin.

Just as no one disputes nowadays the existence of nutritive disorders in hysteria, in the same way no one can deny that in certain forms of neuralgia, without neuritis, the same kind of disorders may arise. Now, is not the most rational way of explaining these disorders that of granting the central theory of neuralgia? Under these circumstances it is easy to see that the morbid irritation extends from the original nucleus of the diseased nerve to the original nuclei of the neigh-

boring nerves, which will manifest their implication by creating nutritive disorders *loco dolenti.*

In the third place, a number of diatheses, and in certain altered conditions of the blood, give rise to neuralgic pains, unless we admit that the spine is affected primarily, how can we understand why these diatheses and modifications of the blood should affect one nerve more than another, and, in some cases, only a few centimetres, or even millimetres, of a given nerve?

Fourthly, it is known that neuralgic pains are connected very closely in different ways with hereditary neuroses. Now, the latter are undoubtedly localized in the nervous centres; how, therefore, could their effects be other than central?

The theory of the central seat of neuralgic pains explains most satisfactorily, (and is the only theory that does so) the way in which such pains jump from one spot to another, alternate from one side to the other, and pass rapidly from this nerve to the next. We know how near to each other in the spinal cord are the original threads of the different nerves, and can consequently understand with readiness how the painful irritation of one nerve can extend with the greatest ease to its neighbor in the spinal cord.

After all, the daily practice of medicine supplies the central theory of neuralgic pains with a decisive argument. It is a matter of common occurrence that cases of neuralgia of the trigeminal, sciatic, or superficial nerves, that have stubbornly resisted the action of various local anæsthetics and different forms of counter-irritation, disappears as if by magic after only a few days' use of bromidia. This extraordinary result is readily explained by the well-known physiological effects of the active elements of bromidia. Purified brom. potass. and chloral, cannabis indica, and hyoscyamus; for it must be remembered that they act on the cerebro-spinal centres. — *Bulletin General de Therapeutique,* Paris.

PROFESSOR LIEBREICH ON MINERAL WATERS.

The *British Medical Journal* reports that in a paper on Artificial and Natural Mineral Waters, read by Professor Oscar Liebreich at the Balneological Congress recently held in Berlin, he began by asking:—Is chemistry sufficiently advanced yet to produce artificial mineral water equal in all respects to the natural water? The answer is negative. The artificial production of mineral waters is a much more difficult matter even than the production of alizarine, indigo, &c., and the analyses even of the most renowned analysts, fall short of the full contents of the water. In the natural mineral water, on evaporation, there is always a residium which is not contained in the analyses of the artificial mineral waters. The carbonic acid gas which furnishes the effervescence of natural mineral water exists also in the form of "carbonic acid hydrate." This has been inferred from the existence of another combination derivative from it, namely, carbonic acid ethyl, which is probably contained in champagne and in other alcoholic effervescing drinks, and is known for its agreeable taste. It may be supposed that the action of an hydric carbonic acid gas is different from that of carbonic acid hydrate. "Even the best manufactured mineral waters," Professor Liebreich points out, "differ from the natural ones in taste and value; this difference it is not easy to explain." He concludes by observing that, "As to the so-called 'indifferent springs, it is a mistake to speak of them as of minor value." It must be remembered that they, too, contain mineral ingredients, if only in minimum quantities, which counteract the effects of perfectly pure distilled water. Even hydropathy is a mineral water treatment, for if the water used were without traces of mineral substances it would be poisonous. This has been sufficiently proved elsewhere.

Hard to Please.

Buyer.—"This dosen't seem to be a very good fit."

Dealer.—"Vot do you egspect for two tollars and a helluf? An attack of ebilepsy?"—*Brooklyn Eagle.*

SELECTED FORMULÆ.

Abscesses.

℞ Calcii sulphidi..... gr. i
Sacchari lactis..... gr. x
Misce et fiant chartulae..... No. x
Sig.—Take one powder every two hours.

Tincturæ opii deodoratae..... ℥i
Tincturae calumbae..... ℥iv

M. Sig.—Take a desertspoonful every two or three hours.

—Martin.

Diabetes.

When gluten bread is used the following formulæ is useful to make up the deficiency in phosphates:

℞ Calcis phosphat..... gr. iij
Magnes. phosphat..... gr. ss
Potassii phosphat..... gr. iv
Ferri phosphat..... gr. ss
Acid phosphoric (60 per cent)..... m vj⅝
Aquae ..... qs. ad. ℥i

M. Sig.—One dose, to be taken daily well diluted.

— William Pepper.

Treatment of Pain in Eye-disease.

When the pain is of corneal origin, Dr. E. Jackson employs one of the two following solutions:

℞ Neutral sulph. atrophine,
Muriate of cocaine.....āā gr. j
Distilled water..... ℥ij

M. Sig.—Instill one drop of this solution into the eye every four to six hours.

℞ Sulphate of eserine..... gr. ⅛
Muriate of cocaine..... gr. iss
Distilled water..... ℥iv

M. Sig.—Instill a drop into the eye every four to six hours.

— Western Med. Reporter.

Ingrowing Toe-nail.

℞ Muriatic acid,
Nitric acid.....āa ℥j
Chloride zinc..... ℥j

M. Sig—Apply 1 drop to the affected part once a day. This gives instant relief to the pain caused by ingrowing toe-nail.

—The Prescription.

Bright's Disease.

In threatened uræmia Professor Da Costa recommends:

℞ Caffeinae..... gr. ij
Sodii benzoatis..... gr. x
Syr. aurantii..... q. s.
Aq. destil.,.....ad ℥ij

M. Sig.— Take 1 ounce every four hours, largely diluted in water.

Coll. and Clin. Record

Dressing for Abdominal Operation Wounds.

Dr. Howard A. Kelley, of Baltimore, uses:

℞ Squibb's ether, or washed ether, and alcohol, absolute..... eq. parts
Bichlor. of mer. (Merck's recryst.), enough to make the solution..... 1-16,000.
Anthony's snowy cotton..... enough to make a syrupy consistence, added in small pieces, stirring.

As soon as this is poured over the wound evaporation begins to take place at once, and the celluloidin hardens, gumming the gauze ast to the skin. To avoid delay in waiting for this to grow quite hard, and to prevent adhesion to the cotton applied above it, the whole surface is freely dusted over with a finely-powdered mixture of iodoform and boric acid:—

℞ Pulvis iodoformi..... ℥j
Acidi borici..... ℥vij

M. Exactissime
Sig.—Dust freely on wound.

This powder is of itself an invaluable protective. He uses it constantly in obstetric cases, separating the labia and throwing it into the vagina, where it acts as a guard to the vaginal outlet against septic invasion from without.

—Am. Jour. Obst.

Battery Fluid.

℞ Potass bichromat..... ℥iij
Aquae..... ½ gal.
Acid sulphurici..... ℥ vj ss

Allow to stand six hours before using.

—Ex.

Battery Fluid.

Dissolve 1½ ounces of Bichromate of Potash in twenty-four ounces of hot water and add ¾ ounces of Saltpetre —let this cool, then add 3 ounces of Commercial Sulphuric Acid, cool again and add a solution of ¼ ounce of Bisulphate of Mercury in 3 ounces of cold water. This gives Oij of fluid. Do not use until cold.

— W. H. Bricker-

Dysentery, (in Chronic Dysentery).

℞ Cupri sulphatis..... gr. j
Pulveris opii..... gr. iij
Quininae sulphatis..... gr. xxiv
Misce et fiat pilulae..... No. xij
Sig.—Take one pill 3 times a day.

—Joy.

Dysentery, (in Acute Dysentery).

℞ Cupri sulphatis..... gr. ss
Magnesii sulphatis..... ℥i
Acidi sulphurici diluti..... ℥i
Aquae destillatae..... ℥iv

M. Sig.—Take a tablespoonful every 4 hours.

—Bartholow.

Mercurial Stomatitis.

Dr. Feibes regards dentifrice powders and gargles as the best means of preventing mercurial stomatitis during a "course" of mercury. He uses the following powder as a dentifrice:

℞ Cretae preparat..... grms.xxxij
Potass chlorat,
Corticis cinchonae rubrae.āā grms.xvj
Ratanhiae..... grms x
Sapon. medical..... grms.xxiij
Essent. menth. piperit..... grms.iij

M.

As a gargle he employs:

℞ Alumin. acetat..... grms x
Aq. destillat,
Aq. flor. aurantior.....āā grms.cc

M.

If the gums become senistive they may be sponged three times a day with:

℞ Tinct. myrrhae,
Sinct. nuc. gall.,
Tinct. ratanhiae.....āā grms.v

M.

CURRENT LITERATURE REVIEWED.

THE OPHTHALMIC REVIEW

For March has an original paper by John B. Story, on

Cases of Glaucoma in Young People.

As primary glaucoma before middle age is of such rare occurrence, the five cases reported are of more than ordinary interest. The patients ranged from 13 to 35 years of age. "The first case is not one of primary glaucoma in the strictest sense of the term" Case 1—"Acute glaucoma after subconjunctival injection of cocaine in a girl of 13." The patient was suffering from convergent strabismus and hypermetrophia. In May, 1890, the tendon of the right internal rectus was divided under cocaine anæsthesia, the pupils at the time being widely dilated by atropine used some hours previously. About two hours after the operation she was attacked with acute glaucoma, intense pains and photophobia. Frequent instillations of eserine in about two hours reduced the tension to normal, the pupil was contracted to about half its former size and all pain was gone.

About a month later the left internal rectus was tenotomised, and although no atrophine was used, and two minims of eserine were instilled at the time of the operation an exactly similar attack of acute glaucoma occurred in this eye about two hours after the operation. It took 4 m. of eserine every quarter of an hour to cure this attack of glaucoma which lasted for one hour. Case II. "Chronic inflammatory (?) glaucoma in a woman of 18." When first seen in March, 1890, this patient had been married one month, and stated that her sight had failed subsequently, with pains in the eyes, although it was afterwards elicited that three months previously she had noticed "blue rims to lamps." It was a typical case of glaucoma. Right eye—hand reflex in temporal field. Left eye—fingers at 0.5 m. in temporal field. A large sclerotomy was performed upwards in each eye, and two days afterwards T. which had been T.+2 in both eyes was reduced to T.n. When seen two years later the patient's vision in right eye was about the same as before the operation, but with the left she could count fingers at 2 m. and decipher Wecker's type No. 8. Case III. "Acute glaucoma of one eye in a woman of 35." Case IV. "Chronic inflammatory glancoma in a man of 30." This patient lost the sight of his left eye every evening. At the time of being seen Nov. 16, '892, left eye V=5/10? whilst right eye √=5/5. His mother had noticed his left pupil getting big at the time when his sight grew dim. He had very shallow anterior chambers, and quite microphthalmic looking eyes; corneal diameter =11 m. m. R and L Tn R and L., as also fundus. Venous pulsation in left disc. Ordered boric acid and nitrate of pilocarpine. On December 3rd, he returned to say that he was then suffering an attack—the second since using the pilocarpine, which had evidently done good, as the attacks vere previously of daily occurrence. Left pupil was wider than right T+2. The left fundus exhibited both venous and arterial spontaneous pulsation. The larger arteries pulsated both on the disc and for some distance also in the surrounding retina. On the next day, after using eserine the previous night, the pupil was contracted, the tension was normal and the symptoms of colored haloes round lights and dimness of sight had quite disappeared. The pupil was too small for thorough ophthalmoscopic examination, but so far as could be seen no pulsation was present in the retinal vessels. On Feb. 1, 1893, the patient presented himself with an attack of a novel description. He had had no attack Dec. 3, 1892 and had used pilocarpine drops daily till January 30, when he forgot to put them in. That night he got an attack, in his opinion, exactly like the one of Dec. 3, but it continued unabated except in one respect, that the pain which marked its commencement had subsided. The eye (left) had a zonular vascularity; dilated pupil; V=5/30. Disc slightly hazy, but cornea clear with no keratitis punctata; very shallow anterior chamber, no visible pulsation, and to Dr. Story's astonishment, T—1. Next day V rose to 5/15 but T remained —1. On March 6th, the patient had another distinctly glaucomatous attack with +T 1, venous and arterial pulsation, dilated pupil and keratitis punctata. He was advised to submit to iridectomy. Case V. "Chronic inflammatory glaucoma in a man aged 34, associated with keratitis punctata." When first seen on Dec. 3, this patient complained of a fog before his right eye and a rainbow halo around light V=5/15 T+1 whilst left eye had V=5.7.5. T n. In this case eserine was used for several weeks with evident improvement, but soon after the myotic had been discontinued he had two relapses and on January 14th, an iridectomy was performed upon the right eye. Six days after the operation, the eye was practically well, when unfortunately, during his sleep, the patient let his hand fall upon it, and he awoke with intense pain, to find the eye completely blind. The wound had been burst open and the anterior chamber was filled with blood clot T+1. In a fortnight all trace of blood had disappeared. T n. media clear; V=5/50; after another week V+2 D cyl=5/10 T n.

In his comments upon these cases the author remarks :—"Priestly Smith regards a narrowing of the circumlental space as the underlying cause of glaucoma, and the determining conditions may be either abnormally large lens, an abnormally small ciliary region, or an abnormal enlargement of the ciliary processes. It is unlikely that an abnormally large lens was present in any of the causes here recorded. The age of the patients renders such a supposition im-

probable, and the only case which shows any evidence of an abnormally small ciliary region is case IV, in which the diameter of the cornea was only 11 m. m. The diameter in all the others was above the average."

This paper is followed by a report of three cases of "Congenital Ptosis with associated movements of the affected lid," by Walter N. Sinclair. The writer says: "Some fifteen cases only of this curious condition are on record, and it will be noted that all these three cases agree in the following particulars: (1) There is congenital Ptosis. (2) The *left* upper lid is affected. (3) While the eyelid cannot be voluntarily raised, it moves upwards freely when certain of the masticatory muscles are thrown into action." This is followed by a very able abstract of an important article covering more than 200 pages of Von Grafe's Archiv., by O. Schirmer (Halle) entitled "A clinical and Pathological study of the Pathogenesis of Sympathetic Eye Inflammations." After an exhaustive condition of the exciting causes of sympathetic eye inflammation the author seems decidedly to favor the theory that the inflammation is due to "bacterial migration" and not to "nerve irritation." A direct migration from the one eye to the other appears to be the probable course. "Whether the path lies along the optic nerves or through some other channel or through both, remains uncertain." Our author considers that an eye which is blind, and which is in the condition to excite sympathetic inflammation should be exercised without waiting for any sign of sympathetic irritation; "or if sympathetic inflammation has already broken out, the exciting eye, if blind, should be removed." "If the sympathetic inflammation breaks out while the exciting eye still retains some vision, the exciting eye must not be excised." "The sympathetic inflammation itself appears to be best influenced by sweating, mercurial inunction, warm compresses, darkness, atropine, and absolute rest of the eye." This number of the *Review* concludes with a reference to Uhthoff's paper "On the Anatomical changes underlying the Ocular disturbances of Cerebral Syphilis."

THE CANADIAN PRACTITIONER

for May contains a paper by E. Herbert Adams, M. D., D.D.S., on

Alveolar Abscess.

In regard to the diagnosis, it is easy in most cases but in some forms it seems to be a matter of difficulty for the general practitioner. The author reports several cases which were mistaken for diphtheria, carbuncles, strumous enlargement, etc.

A simple means of testing whether a tooth is abscessed is by rapping the tooth with an instrument. If it should prove tender on pressure, the apical pericemental membrane is inflamed, and the root of the tooth probably abscessed.

Abscesses most frequently occur on teeth with dead pulps. In such teeth the natural translucence of the tooth is gone, the dentinal tubuli being filled up with dead matter, due to the disintegration of the pulp. The dark color and opacity is often very marked, but is occasionally so slight as to escape notice. If, however, the patient is placed in the sunlight and the rays of light reflected on the teeth by means of a mirror, a slight opacity will be noticed.

The patient's notice is often directed to a painful tooth as a possible cause of the trouble, but it must be remembered that neither a decayed tooth nor pain need necessarily be present. The pulp may have died from some other cause, and the diagnosis can be made by the opacity of a tooth and its tenderness on pressure.

The *treatment* is comparatively simple in most cases, and consists in the evacuation of the contents of the pus cavity, and in injections of antiseptics until it is rendered thoroughly aseptic.

In the more simple cases this is readily accomplished by a dentist drilling through the root canal and thus allowing an exit for the pus,and an opening through which antiseptics can be injected. It is rare, indeed, that a skilled dentist cannot successfully treat even the worst cases by this means. Of course, if the offending tooth is for any reason considered of no value, the simplest method of cure is its removal, when the abscess will, as a rule, heal without any medication.

In some cases a simple way is to drill through the alveolus, just above the root of the tooth, and thus give an exit for the pus, and an opening for antiseptic medication. If it is desirable to keep this sinus open, a simple method is to place a pledget of cotton, soaked in a strong solution of carbolic acid, in the sinus.

In acute alveolar abscess where there is much swelling of the face, it is often well to endeavor to cause the abscess to point on the buccal surface of the gum over the root of the abscessed tooth. This can often be accomplished by the application of a counter-irritant, such as capsicum or cantharidine, to the gum overlying the root of the affected tooth. A roasted fig or raisin is said also to accomplish the same result.

All applications of hot fomentations, or poultices, or counter-irritants to the external surface of the face should be religiously avoided, and if the abscess seems to have a tendency to point externally a free incision for the pus should be made *in* the mouth, and the counter-irritants or other medicaments applied *in* the mouth. This will prevent many an opening on the face, and its consequent scar.

Constitutional treatment should not be neglected where indicated. A saline cathartic will often assist in hastening the removal of an acute abscess.

The author concludes his paper with the warning not to yield to the temptation to open the abscess on the face, when it points there, on account of the resulting scar and disfigurement.

Prophylaxis is of importance in the prevention of alveolar abscesses, but this belongs largely to the domain of the dentist. It

should, however, be the duty of every physician, whenever he finds decayed or offensive teeth present in any patient, to impress on them the importance of visiting their dentist and having their teeth attended to.

Dr. Samuel Theobald contributes a paper on

Radical Cure of Stricture of the Nasal Duct,

Advocating the passage of the larger sizes of probes on account of the danger of producing a false passage by means of the smaller ones.

His method of operating is first to anæsthetize with cocaine and then pass a small probe, No. 2 usually, through the puncta, and canaliculus to look for, and finding it, to overcome any stricture at the juncture of the canal and sac. This facilitates the entrance of the probe-pointed canaliculus knife into the sac. Having slit up the canal he then passes a No. 5 or No 6 probe, or a smaller one if he fails with these. He anoints the probes with vaseline containing 10 per cent. of cocaine. Having surely entered the sac, we need not hesitate to use force in passing the stricture. He has never seen any serious consequences. Rarely he has had while using the small probes an ecchymosis of the lid, and once or twice slight inflammatory reaction. He does not think it advisable to probe daily unless compelled to do so for want of time. It may excite too much inflammation. Every other day is his custom. He increases by one number each time, skipping a number if very freely passed, or dropping back one if too tight. In two-thirds of all cases, including children, he has used a No. 16. Having reached the largest he intends to use, he then increases the intervals. The only objection he knows to the treatment is that the duct may remain too pervious and air pass freely when the nose is blown; but such inconvenience is, he thinks, very small.

In addition to probing, he prescribes collyria to be used three times a day; the most useful being a solution of bichloride of mercury 1-12000. Next to this, he prefers a solution of alum 10 grains to the ounce. He does not attack a fistula or carious bone, believing that they soon will take care of themselves if the passage is open. Patients may be taught to probe themselves with the larger probes. Strictureotomy has never appealed to him as rational treatment, nor has he ever had reason to destroy the lachrymal sac.

Under "Clinical Notes," Dr. J. N. E. Brown reports a case of

Compound Comminuted Fracture in the neighborhood of the Knee Joint: Recovery with Movable Joint.

The treatment adopted was as follows:

The wound (from which there was considerable venous oozing) was flushed out with hot water, and subsequently with 1-4000 bichloride of mercury; three large drainage tubes were inserted, and a few points of silk suture introduced. An antiseptic dressing, consisting of moist bichloride gauze with absorbent cotton was applied. An interrupted long splint, extending from the axilla to the foot, was applied, with extension.

The patient recovered with an amount of shortening less than one inch: flexion and extension are restricted, the maximum amount of movement being through an angle of about ten degrees; when extended as far as possible, the limb is not quite straight, but is nearly so; an extensive cicatrix marks the site of the original wound.

Dr. William Oldright reports "a Case of Pneumo-hæmatothorax" which followed an injury. Patient recovered.

Dr. William Crawford reports a "Case of Placenta Previa with tendency to Post-partum Hemorrhage.

THE PACIFIC MEDICAL JOURNAL

for May contains a paper by Dr. John W. Robertson on

The Keeley Cure of Alcoholism.

The author reiterates the statement, now so frequently made as to become "a back number," that the basis of the treatment is strychnia. In his investigations of the subject, he arrives at precisely the same conclusions as Dr. Chauncy F. Chapman, whose article on "The Bichloride of Gold Treatment of Dipsomania" first appeared in the *Chicago Medical Recorder* and was reviewed at length in THE MEDICAL AND SURGICAL REPORTER for March 25, 1893.

The strychnine is the remedial basis of the injection and its virtues were fully recognized long before Keeley robbed it of its ancient name and honorable connections and re-christened it under the bastardized title of "Bichloride of Gold." One-fortieth of a grain of this drug is injected four times daily. In addition there is given for internal administration a mixture the basis of which is the well-known red extract of cinchona, which was long ago vaunted as a cure for alcoholism. The author advocates the use of strychnia not only in the lighter forms of alcohol poisoning but also for controlling delirium, stating that it is superior to morphia or chloral. In concluding his article he speaks as follows:

"My experience with the treatment of alcoholism and my acquaintance with alcoholics have been large, caused by my temporary connection with the Home of Inebriates. I am free to confess that I succeeded but indifferently well in the treatment of this disease, though I used the drugs I have so highly commended. Even when treating the same patient that was afterward benefited by a gold cure course, there was an element lacking which they supplied, viz, mystery as to the drug used and a positive assurance that they were receiving specific treatment. Another reason was that patients were unwilling to spend a month in getting well, and I could not give them the desired change of air and surroundings. The first reason for my lack of success no honest man can overcome, the second could be easily obviated, but without faith it is but a temporary expedient."

"If time should prove that the Keeley system does possess some eminent merits do

not confound them with inhibitory influences. At last we are beginning to recognize the value of suggestion, hypnotic we call it, and it is this feature of the cure which may have a restraining influence on certain of the "graduates." Take away the mystery, and expose the bichloride treatment to the search light of truth, and then the value of the cure has departed and in its place stands a temporary aid and first guide in the art of curing drunkenness. With such a title no institution can flourish, for the drunkard knows his weakness, and, unaided, would never attempt to take the first steps necessary to his restoration. In conclusion I repeat that Keeley has no specific, no secret further than the secret of humbug, and if he made known his "cure" it would fall to pieces as do bones long entombed when exposed to air."

"I will match Keeley's secret as regards remedial value and scientific acumen with one I recently found in the 1601 edition of Philemon Holland's translation of Pliny: 'For to avoid drunkennesse take the lungs of an hog, be it bore or sow, it matters not, in like manner of a kid, and rost it; whosoever eateth thereof fasting shall not be drunk that day how liberally soever he take his drinke.'"

The remaining articles in this issue are The Presidential Address delivered before the Medical Society of the State of California, by Dr. W. E. Taylor; and the Report of the Committee on Obstetrics and Puerperal Diseases to the same body by Dr. Charlotte B. Brown. Antisepsis is insisted upon. The use of ergot, the report states, is more and more condemned by late writers. Hemorrhage from atony can generally be overcome by hot flushings of the vagina, or even the uterus, using a return catheter, much more promptly than ergot can act. But if this fail, the introduction of a piece of iodoform gauze acts at once and with no danger. Placenta previa having been diagnosticated, temporizing is out of place—labor should be induced at once. For the prevention of ophthalmia in the new born, the use of a boracic acid douche to the eyes is advocated.

PERISCOPE.

MEDICINE.

Infantile Paralysis.

At first, according to Dr. J. Simon, external methods are used, slight revulsion over the spinal cord about the origin of the roots of the nerves, with dry cups or application of croton oil mixed with some menstruum; or mustard leaves rather than the cautery points and the other more painful methods of vesication. Next give stimulating baths (in bed), using vapors, etc. Thirdly, sedation of the nervous system by chloral, aconite, or conium. In the second week combine electricity with tonics as follows: Galvanization by weak, continuous currents, (two to four milliamperes). Apply the positive pole by slipping it on the shoulder, and put the negative pole in a basin of water slightly salted, into which the hand is put, use this for eight to ten minutes, and notice that the positive pole does not blister the shoulder. If it gets too red reduce the strength of the battery. Later, use the faradic current as a change, but with weaker current. Slight massage and friction may be made also. Give the following:

℞

Tinct. Nux Vomica.....	15 grains.
Tinte. Colombo	1½ drachms.
Tinct. Cascarillæ.....	1½ drachms.

In eight or ten days commence an arsenical treatment by a half to one milligramme of sodii arsenias.

During convalescence use sulphur baths or salt-water baths, or sea baths, for three minutes at a time only.—*Arch. of Ped.*

SURGERY.

Intravesical Injections of an Ethereal Solution of Iodoform in oil.

In the treatment of either acute or chronic cystitis, the above method has been employed by Dr. Okev Blom, Finland, with excellent results (*Ann. d. Mal. d'Org. Genito. Urin.*)

He advocates the use of a solution consisting of one gramme of iodoform dissolved in seven grammes of sulphuric ether, to which seven grammes of olive oil are added. The oil is added to modify the irritation produced by ether on the vesical mucous membrane. This is injected into the bladder and allowed to remain as long as possible. The frequency with which the injections are given, depends on the nature of the case.

In some patients they should be given daily; and others every other day; and others only require to have the injections made once in several days.

The most marked improvement was shown in acute cases of gonorrhœal origin.

It is not claimed that this is a universal remedy for cystitis, but in abo ut eleven cases out of twelve its action is most efficient.

During the treatment the patient should abstain from alcoholics and live as much as possible upon a milk diet.

Syphilis and Wounds.

In syphilitic subjects, wounds, as Dr. G. Frank Lydston has shown, take on decidedly abnormal action. In the treatment of these cases Dr. A. C. Bernays of St. Louis has found calcium iodio and bromide (elixc. iodo-brom. calciumdemp.) of great value.

GYNECOLOGY.

Laceration of the Cervix.

Dr. Fraisse (*Nouvelles Atch. de Obstet. et de Gyn.*) holds that every delivery at term in a primapara is accompanied by a laceration of the cervix. When it is of the first degree it undergoes immediate repair, and is shown only by a transverse elongation of the os.

The first symptom of severe laceration is hemorrhage, appearing previous to expulsion of placenta and reappearing after the third day of labor is completed. The blood comes in jets, and is fluid and bright red. Dr. Fraisse formulates this statement: If the uterus is firmly contracted, and there are no external lesions, any abundant hemorrhage may be assumed to have its origin in a laceration of the cervix which extends beyond the insertion of the vagina." Such a wound greatly increases the dangers of local and general infection.

The treatment of the hemorrhage consists in pressing the cervix upward towards the symphysis by means of the left hand introduced into the posterior cul-de-sac, the right hand seizing the body of the uterus externally and maintaining it in a position of anteflexion for about ten minutes. One such maneuver is usually effective, but it may have to be repeated; should it fail, a continuous catgut suture may be at once applied.

(338) Ichthyol in Gonorrhœa.

Jadasson (*Deutsch. Med. Woch.* 1892, Nos. 38, 39) speaks highly of ichthyol for gonorrhœa in women as well as in men. In thirty-seven cases occurring in females the results of treatment were excellent. Ichthyol can readily be applied to the cervix, and also, later on in these cases, to the endometrium with an ordinary Playfair's probe covered with wool; a 10 per cent. ointment is sufficient. The probe may also be used for the urethra; a weaker preparation—from 1 to under 10 per cent—is needed. It may, however, be injected, and, in some cases, the urethra should be packed with gauze dipped in the ichthyol, and introduced through a urethral speculum.—*Brit. Med. Jour.*

ARMY AND NAVY.

U. S. ARMY FROM MAY 21., 1893, TO MAY 27, 1893.

Leave of absence for twenty-five days to take effect on or about June 5, 1893, is hereby granted Major D. G. Caldwell, Surgeon, U. S. Army.

The leave of absence on surgeon's certificate of disability, for treatment in the Army and Navy General Hospital, granted Capt. Freeman V. Walker, Assistant Surgeon is extended to June 30, 1893.

First Lieut. James Kennedy, Assistant Surgeon U. S. Army, (recently appointed), will proceed from Troy, Abbeville Co., S. C., and report in person to the commanding officer, Fort Riley, Kansas, at that post.

By direction of the President, Major John O. Skinner, will report in person to Col. Henry W. Closson, Fourth Artillery, president of the Army retiring board at Washington Barracks, D. C., when required by the board for examination by it.

First Lieut. Alexander N. Stark, Assistant Surgeon, will proceed from Norfolk, Va., and report to the Commanding Officer, Fort Monroe, Va., for duty at that post.

First Lieut. John S. Kulp, Assistant Surgeon, will proceed from Wilkesbarre, Pa., and report to the Commanding Officer, Columbus Barracks, O., for duty at that post.

First Lieut. James D. Glennan, Assistant Surgeon U. S. A., is relieved from further duty in the Department of Texas, and ordered to join his proper Station, Fort Sill, Okla. Ty.

First Lieut. Edward L. Munson, Assistant Surgeon, will proceed from New Haven, Conn., and report to the Commanding Officer, Jefferson Barracks, Mo., for duty at that post.

First Lieut. Charles E. B. Flagg, Assistant Surgeon, will proceed from Indianapolis, Ind., and report to the Commanding Officer, Presidio, of San Francisco, Cal., for duty at that post.

First Lieut. Charles Lynch, Assistant Surgeon, will proceed from Syracuse, N. Y., and report to the Commanding Officer, Fort Omaha, Neb., for duty at that post.

First Lieut. Guy C. M. Godfrey, Assistant Surgeon, U. S. Army, ordered to proceed to Fort D. A. Russell, Wy., and report in person to the Commanding Officer of that post for duty.

The World's Fair.

FINAL ARRANGEMENTS FOR THE SALE OF TICKETS VIA THE B. & O. R. R.

For the benefit of those desiring to attend the World's Fair the Baltimore & Ohio Railroad will sell Excursion tickets to Chicago and return, at all stations on its line, at low rates. Tickets will be on sale until November 1st, and will be valid for return journey until November 15th, 1893. They provide for a reduction of 20 per cent. below regular rates. These ticket will be valid only for continuous journey. Tickets at higher rates will be sold that will permit holders to stop over at Baltimore, Washington, or any other point, going and returning.

Besides the opportunity of visiting Washington, a privilege afforded by no other route, tourists via the Baltimore & Ohio Railroad will traverse the historic Potomac Valley, the theatre of the war between the States. At Cumberland they will be offered a choice of routes, via Pittsburgh, or across the Allegheny mountains, 3,000 feet above the level of the sea and via Deer Park and Oakland, the famous summer resorts. The scenery along the Baltimore & Ohio route is the most picturesque in America. Pullman accommodations may be reserved in advance of journey. For rates and information apply to nearest B. &. O. Ticket Agent, or Chas. O. Scull, General Passenger Agent, Baltimore, Md.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.
(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Sodic, one or two pillets when three times a day.

Pil. Lady Webster.
(WM. R WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.
(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.
(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica ⅛ gr. | Dose—1 to 3 pills.

Pil. Antisepte Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES

Calculi Dissolved

BY THE

Buffalo Lithia Water

Illustration of the Calculi referred to by Dr. Claiborne. The engraving was made from a photograph and represents the exact shape of the Calculi; they are four times size of above.

Dr. John Herbert Claiborne, of Petersburg, Va., *ex-President and Honorary Fellow Medical Society of Virginia, in a letter, dated September 3, 1892, to Dr. E. C. Laird, Resident Physician at the Buffalo Lithia Springs,* says:—"I send by this mail a box of Calculi, passed at various times within the last year by Hon. T. J. Jarratt, our former Mayor, whilst drinking the Buffalo Lithia Water. They give him but little pain now when passing. I have never critically examined the broken Calculi, passed in such quantities from Mr. Jarratt's bladder, but am under the impression that the most of them are magnesian phosphates. There were specimens, however, which presented the appearance of oxylates, and some, I remember, impressed me specially as being uric acid. I do not pretend to account for the mode of their solution by the Buffalo Lithia Water. There is nothing in its analysis which would warrant such results; but the results are there, and seeing is believing. I can only suppose that **in Nature's alembic there has been some subtle solvent evolved, too subtle to be caught by our coarse re-agents, which make this wonderful disintegration.** 'There are many things in heaven and earth not dreamt of in our philosophy,' and his is a short creed who only believes what he can prove or explain."

Water in cases of one dozen half-gallon bottles $5.00 f. o. b. here. Sold by all first-class druggists.

ADDRESS ON HYGIENE.*

SAM'L G. DIXON, M. D.†

A few days ago when I came to reflect upon the subject selected by our able President as the one upon which I was to address you I was not a little perplexed. For me to presume to teach a learned body of Medical Doctors, such as have here congregated, regarding the most important branch of Medical Education would be unpardonable. I can, therefore, only hope by chance to refresh your memories upon a few points in Sanitary Science. As a teacher of medical students I have seen fit to divide the subject into *personal*, *general* and *public* hygiene.

Including under personal hygiene:

Inheritance,

Hygiene of various periods of life,

Prevention of mental, moral and emotional diseases,

Prevention of sexual diseases,

Hygiene of clothing,

Hygiene of occupation, etc.

UNDER GENERAL HYGIENE.

Hygiene of foods—
- Practical dietetics,
- Food adulterations,
- Food decompositions,
- Accessory foods, etc.,
  - Stimulants and narcotics, (Intemperance.)

Hygiene of water—
- Water supply,
- Potable water,
- Balneology.

Hygiene of Dwellings—
- Air, humidity.
- Lighting,
- Heating and ventilation,
- Plumbing,
- Drainage and sewerage,
- Location and soil—
  - Ground air,
  - Ground water,
  - Soil pollution.

Climatology,
Medical Meteorology,
Animal parasites (Examination of meats, etc.)
Vegetable parasites (Bacteria.)

PUBLIC HYGIENE.

Infectious diseases,
School Hygiene,
Quarantine—means of combating diseases,
Disinfection,
Hygiene of hospitals, prisons, etc.,
Vital statistics,
Legislation of public measures,
Vaccination, etc.,
Disposal of the dead.

This scheme may appear too comprehensive for a student of medicine under our present short graded courses of three years, yet, as it is not in the least too general I would be pleased to see it introduced into the curriculum of every medical teaching institution of our Keystone State, and at the same time to have its standard well protected by a learned State Board of Medical Examiners. However much I may advocate this standard in our medical schools, I can assure you that my address to you will be exceedingly short. I will not presume to air my own erudition in a comprehensive lecture on sanitary medicine, as I feel sure it would be at the expense of others who are here, I have no doubt, to teach us that which has not heretofore been known to the medical

*Read before State Medical Society, Pennsylvania, May, 1894.

†Prof. Bacteriology Acad. Nat. Sciences, Phila.

profession. To avoid inflicting tediousness upon you my fellow members of the State Medical Society of Pennsylvania and for brevity's sake, I will merely attempt to refresh your memories upon a subdivision of my comprehensive scheme of preventive medicine, which will be *air*. In considering the importance of this element to sanitary science we must recognize that man's surroundings are, and ever will be, impregnated with minute life which will, when brought into relationship with a favorable nidus, at least direct either functional or comparatively harmless pathological conditions into maladies which nature may neither exist under or overcome. Again, it would appear, so far as we can determine from artificial experimentation, that this micro-organic life can *per se*, when introduced into healthy tissues, disturb the normal affinities of the animal economy. This being admitted, we must accept the situation and prepare ourselves for war with this minute life by first building up healthy, vigorous tissues, for, the instant we permit them to drift from a normal condition they at once offer a nidus where pathogenic organisms may feed, grow, reproduce and form toxic substances which will so disturb the higher animal organic life as to cause dissolution. To grow tissue sufficiently vigorous to destroy these germs of disease as they enter the body under ordinary circumstances, we will be compelled to call to our assistance each and every hygienic measure known to man. We must enforce proper mental and moral training, suitable clothing, occupation, diet, bathing, sanitary dwellings, urban parks, proper food, vaccination and above any other one element *pure air*. However, as I have already stated that I do not intend taking advantage of the privilege granted me by this society, I must and will confine myself to the factor that above all others takes a high position in governing health and disease and at the same time the one most frequently lost sight of by both the layman and physician. The high place I give air as a sanitary factor may be severely criticized, for I do not know of any means by which we can measure the influence of isolated factors in favor of and antagonistic to the health of animal life. I will, however, for my purpose on this occasion venture to place air on a high plane, as our whole vital process is dependent upon this one element. To appreciate the importance of this, the chief factor of organic existence in relation to both health and disease, we must ever keep before us, in at least a superficial way, the physiological processes dependent upon this mechanical mixture. Animal life demands air through the organs of respiration and transpiration from the very moment it obtains an independent existence until the last act of life is performed. Parkes very truly states that starvation is a matter of days without solids, hours without liquids, but of minutes without air. We must ever bear in mind, that the air, made up of 20.96 per cent. O., 97 per cent. N., and .04 per cent. of carbon-dioxide, a strong man takes into his lungs supplies oxygen to 443,520 ozs. of blood every twenty-four hours. To obtain a full supply of oxygen for the tissues through the red blood corpuscles *all* the physiological functions of respiration must be in health, for this reason we cannot entirely overcome inherited inconsistencies. If there is any reduction in the required amount of this important constituent of the atmosphere, just to *that* degree of loss do the animal functions of the body become impaired and the moment there is an entire cessation of the supply of oxygen, life immediately goes out. It would seem that the nervous system first feels its loss; then the heart, the brain and the digestive system, etc., all become sluggish in their respective functions, the results of which are reflected upon every cell and fluid in the animal body. Physiological combustion is interfered with and consequently the required chemical changes necessary for health do not take place. The blood is loaded with debris and is thereby rendered unable to take up the waste of the tissues, but leaves it as foreign matter to undergo changes and form poisons.

Consumption of the lungs is always to be found in great excess both in man and in the lower animals, who live in such environments as compel the breathing of devitalized air, producing sluggishness of physiological action. It is under this condition that the digestive secretions are impaired and the general physiological combustion reduced so that the body becomes a habitat for germs, called pathological micro-organisms, and they, with their respective methods of digestive processes, affect a

breaking up of the already weakened affinity of the molecules forming the cells and tissues and in some way or other these organic chemical substances are toxic to animal life. The powerful effect of repeated infinitesimal quantities of these poisons, which are often albumoses, is beyond our present knowledge, yet, we have good reason to believe that they cause many chronic changes that insidiously creep upon us, while large doses of them cause death almost immediately. For instance the subcutaneous injection of blood taken from an animal with uræmia produces uræmia in the recipient. Prevention of elimination through the excretory organs will also produce the same result. Gautier and many others have thoroughly demonstrated that animal tissues in process of putrefaction and decomposition invariably elaborate certain alkaloids of very powerful toxetic properties. To-day we know that these toxic albumens are also formed during the life of the animal tissues, and are called leucomaines; any excess of the production of such substances in the animal economy, even in most minute quantities would certainly be very dangerous to health were it not for the eliminating organs. This is demonstrated by an instance just cited in which the kidneys were ligated, and the animal thus affected soon died with symptoms indicating a malady that has received the misnomer of uræmia. The production of the waste is in reality a feature of life. Dr. A. M. Brown very properly said, "Life is a contingent phenomen consisting of partial births and deaths. In the midst of life we are in death," for, scientifically speaking, it must be admitted that the living body always bears with it the components of the dead one. Life only goes on as long as the organic and inorganic work together, and to carry on their functions consistently with health, the normal quantity of oxygen must be furnished the blood in order to form normal waste. The disassimilation that results from overloading the system with debris, because of the blood being deficient in its carrying powers, often results in the production of leucomaines. Impure air often contains these toxic alkaloids that I have said are produced outside of the living tissues, and can be taken into the body through respiration. The decaying organic matter in the air in a Russian hut in the spring time after it has been occupied all winter, will, with many people, bring on nervousness, indigeston and diarrhœas and sometimes typhus fever, either directly or through the agency of minute life. I am convinced from my investigations that no one living in a normal atmosphere, performing that sort of physical exercise calculated to pump a normal quantity of air into the lungs would likely become a victim to typhus fever. Let it be a reproductive poison or not, it is, I have no doubt, favored by impure air, which not only supplies toxics formed outside the body, but also permits them to form in the tissues. If our people had a bountiful supply of pure air furnished to the lungs, we would all, even we bacteriologists, attach less importance to the disease-affecting and disease-producing micro-organisms. On the principle of resistance, man must protect himself against the deadly work of micro-organisms. We cannot directly exterminate them outside the animal body, or as yet see our way clear to overcome their pathogenic characters. If they once gain entrance and establish themselves in their human abodes it is a most difficult task to successfully battle against their action upon the tissues without overcoming the animal economy. For this reason, therefore, we must, as I have said, supply the body with its required amount of oxygen to keep up the highest degree of vitality in every member. Otherwise the secreting and excreting organs will cease to do their full quota of work and the tissues will not continue to undergo that constant regeneration that is necessary for health; the blood can neither carry nourishment to the respective organs nor in turn convey the debris to the eliminating viscera. The importance of pure air for the health of man must be apparent to us all from the fact that the very environments in which the animal kingdom has been evolved is most constant in its supply of this mechanical mixture of oxygen, nitrogen, and carbon dioxide, as they are the constituents of the very element that has permitted the present development of man and the lower animals. Without it we are *a priori* infected by the formation of leucomaines which would otherwise be prevented by normal physiological combustion. I believe we often find an example of the want of a normal elimination

of debris in children living in cities. A child, particularly one with insufficient chest expansion that has been taking considerable exercise in a badly ventilated room, will frequently suffer toward evening with what we call growing pains, and at times with a slight rise in temperature, while *the same child* when submitted to like exercise in country air, where it can obtain sufficient oxygen, will not be subject to the same painful affection. In many such cases it is quite probable that the trouble is brought about by the inability of the blood to furnish enough oxygen to the tissues and to carry away the debris and if this condition is carried on continuously for some weeks, we will have a continued fever due, in all probability, to the formation of leucomaines, or to catarrh of the digestive tract. The physiological process of life not only demands the formation of natural tissues, but also of *normal waste* and the moment the eliminating organs are called upon to battle with foreign matter, their scope of power is limited and the tissues irritated; as for instance, when the kidneys are loaded with uric acid crystals, the results of which we are perfectly familiar with. This condition can be overcome if we have both healthy lungs and nervous system; the latter to transmit normal impulses to the respiratory muscles, and thus furnish the blood with pure air to bring about natural physiological combustion. You may limlt your patient's diet to non-nitrogenous food-stuff, you may wash him out with the free administration of water and you may drug him with any or all of the remedies known to the medical profession that have any relation to a gouty diathesis and find your treatment of little or no avail unless you have the patient exercise in fresh air. Perfect oxidation of the food is the prevention and cure for gout. The changes effected by the artifice of man in the normal uniformity of the composition of the atmosphere is too significant a fact for us to lose sight of when considering a means for the preservation of health and the cure of disease. Pure air breaks up organic matter and renders it both harmless and also useful to each and every form of life that has been evolved in its midst. Without its chemical action upon inanimate matter, heat and energy would not be produced and the world would be without animate things. It creates and supports life; therefore, the moment we overload it with impurities, that moment we interfere with its power to maintain health. Yet, owing to man's present want of apppreciation of the necessity of maintaining the purity of this mechanical mixture for health, I have never found in his habitations an approach to purity in this great life-supporting element. It is mostly deficient in oxygen which is replaced by carbon dioxide and carbon monoxide, toxic, non-toxic, organic, inorganic, matter and frequently by pathogenic micro-organisms.

The carbon dioxide is of course, the least harmful. It being within itself only a negative poison. We do not now believe that the 123 persons that died out of the 146 confined for one night in the Black Hole of Calcutta, nor that the 70 passengers who died out of the 150 that were fastened in the cabin of the steamer Londonderry with the hatches battened down during a rough night in the year 1848, were killed by asphyxiation from carbon dioxide, but that they perished from the animal alkaloids formed out of the organic debris exhaled by the lungs and skin into an atmosphere deficient in that great purifier—oxygen. Organic matter is also taken into our buildings by soil air, our boots, and in large towns and cities, by the very air we are compelled to circulate through our dwellings as the nearest substitute obtainable for nature's atmosphere. The air of Philadelphia this month is so laden with filthy organic matter raised from the dirty alleys, (I say alleys, because they are not worthy the title of streets,) that when the sun's rays strike them as suspended in the atmosphere of a room slightly agitated, you instinctively hold your breath. Not only is this air loaded with filth that undergoes a chemical change and forms compound poisons when retained in rooms deprived of sunlight and deficient in oxygen, but we have also sub-soil air that circulates through earth so poluted with sewage that when brought to the surface you can smell it, with a moderate wind, some 1,000 feet away. This is the condition of the air that circulates through our cellar walls in Philadelphia, the average stones of which they are built containing nearly fifty per cent. of air which is constanly interchanging with the surrounding

atmosphere. Again a large proportion of the floors of hot air chambers of our heating furnaces are built of porous earth. What is the effect of this condition of affairs? Why, the air in the hot air chamber is lighter than the filthy sub-soil and outdoor air, therefore, the heavier outside column forces the poisonous sub-soil air through the floor of your hot air chamber, filling the space with a poluted air. This in turn becomes lighter and is forced through the hot air flues into the living rooms to feed the occupants, and we wonder why we are not typical specimens of the genus Homo. During the early part of this century, Philadelphians were not satisfied with the cess pool and sewage filth they could take into their bodies through the air. The cess pools and sewers were built with what is called dry walls, which are walls constructed simply of bricks with open inter-spaces. The object being to permit the percolation of the effluent through into the surrounding subsoil, the idea being that mother earth was a great and inexhaustable purifier. This, however, was too complimentary, her power was limited and the sub-soil soon became surcharged with filth and through this polluted ground they deliberately laid wooden conduits for water carriers, which in certain strata of earth soon decayed and became very porous, in fact so much so that disease-effecting and disease-producing micro-organisms would pass through their walls into the stream of water, on its way to the drinking tap in the houses of our ancestors. If this condition of affairs existed at present, we might be even more apprehensive than we are of the threatening cholera epidemic. Another substitute for the oxygen that our house air frequently contains is, as I have already mentioned carbon mon-oxide. This gas is a direct and deadly poison, one per cent. of which in a confined atmosphere will unite with the hæmoglobin and deprive the red blood corpuscles of their power to carry oxygen to the tissues, in consequence of which the nerve centres fail to respond to stimulation and death ensues. The usual sources of this gas, which I believe to be one of the great predisposing causes of early decay of our faculties, is the combustion of the substances used for producing heat in buildings for the various purposes of man. It is non-odorous and will pass out through cast iron when sulphurous acid gas, which when present acts as a tell tale, will not escape. Hot air furnaces and stoves for the burning of coal are fertile sources of this poison. Yet, our city fathers in Philadelphia were not satisfied with the small volumes of this insidious poison produced and permitted to escape into the air of our buildings from this source, and they therefore introduced water gas into our mains. This gas must contain at *least* 35 per cent. of carbon mon-oxide and at the same time has a solvent power on a residuary substance that has been deposited in our old pipes from coal gas, which prevented leakage—consequently during the last year our houses have been deluged with this health destroyer. There is no doubt in my mind, but, that much of the so-called diphtheria in Philadelphia last winter was a tonsilitis caused by water gas poisoning. Our people, however, because they are furnished with a better illumination by this gas which is richly charged with carbonaceous material, go on electing to office those who are through ignorance poisoning our bodies and, at the same time, burdening us with as heavy a tax as the English laid upon our colonial ancestors, by charging for this poisonous gas about three times the cost of its production. Deficiency in oxygen and the excess of carbon dioxide and the additions of carbon mon-oxide and organic matter in the air of buildings occupied by man and the domestic animals undoubtedly play a most important part in the etiology of all pathological processes, yet, the injury comes so slowly and continuously that man does not fully realize the presence of the enemy until too late. The people's medical advisers do, however, realize this condition and also the importance of pure air to maintain health and to overcome pathological processes. Therefore it behooves our profession to teach the people, particularly the law-makers of our land, the necessity of having this element, with which nature has so bountifully supplied the organic kingdom, kept pure. Each physician should insist upon his patients refusing to endorse any candidate for public office unless he gives a pledge that he will exert himself to have laws made and enforced to bring about a higher degree of health. It is as important to compel our people to have properly ventilated and lighted houses as it is to

have sanitary plumbing, which latter our laws require. As physicians we forget the scope of our power and neglect our moral and professional duties. It is incumbent upon us to instruct our patients how to preserve health and thereby improve the moral, religious and political standard of this the greatest nation of modern times.

Ill health is the parent of much that is bad in civilized life and it lies in our power more than it does in those devoting their lives to the professions of law and theology to advance the moral condition of our people. There is not a man, woman or child in this great State that is without a physician. He is thrown into the most intimate relationships with his patient and by teaching the proper laws of hygience he can greatly reduce murder, suicide, drunkenness and family feuds. If this is so, why are we not doing our duty? The answer must be that sanitary medicine is not attractive, in fact many of its details are naturally repulsive and not profitable to him, and therefore the physician shuns it in his private capacity and this is wherein he fails, for it is not as a reformer, legislator, or a scientist, but as a family physician that his great power for good in this direction lies. It is in this role that the doctor of the present day is at fault, he does exert himself to legislate, to exhort his fellow physicians, but, as the familiar family doctor, he fails to take advantage of his power to exert a moral influence over his fellowman. The great physician must bridge over the wide gap between science, in the abstract, and medicine as it should be practiced in every day life. Without a moral influence over his patient, he cannot reflect the full power of his scientific knowledge.

In no other profession is the adviser brought into such intimate relationship with his fellow creatures when they are susceptible to advice, unless it be the spiritual adviser whose duties too often come when the question of life is about to be closed. At the word of the physician families separate for years, men give up their trades and vocations. Their domiciles are moved to higher elevations, or to the seashore. Therefore, if we have it in our power to bring about such radical changes as these in the habits of our patients, why is it that our homes, factories, mills, vehicles, hospitals, places of amusement, etc., etc., etc., are so poorly supplied with fresh air. Again why is it that our cities in this great State are permitted to be built up so closely? Where are our urban parks, gardens, and playgrounds which are necessary to keep up the average standard vitality of this great nation? I say nation because it is made up of individual men and women, its power being simply the sum total of the force of the individuals that go to make it up, and the more thickly the inhabitants are settled the lower is the degree of health. It has been said that, all things being equal, the health of a population is in inverse ratio to its density. The only way to overcome this rapidly increasing evil of huddling together is by opening to the people public gardens and open spaces and wide boulevards. A wide avenue is now proposed in Philadelphia, which would not only give to the city as it were, a new lung but it would make a short and attractive walk and drive to the greatest city park in the civilized world. I have heard it spoken of as an ornamental luxury, but I believe it is a crying sanitary necessity, which if once demonstrated to our lay people by its physical opening, would, in a short time, be followed by a request to the authorities for others of a similar nature. Outside of a better sewage system and a mechanical filtration of Schuylkill water I know of no other more crying need in that great city of our State than air spaces and vegetation.

The way in which our towns are being closely built up is disgraceful to our city fathers and reflects somewhat upon the medical profession. Too many poorly ventilated public school houses are at present being erected. They are built upon contracted spaces, without gardens or playgrounds, where the brains of the present generation are overworked and the body starved and poisoned for want of pure air. To pass one of our public school houses in Philadelphia at noon and see the pale faced children playing on the damp brick pavements between two high walls shutting out the rays of the glorious sun, makes one blush with shame for the ignorance of our people. While to enter one of our school houses during session soon benumbs one's brain. During the last winter, young girls in our Normal school fainted away for want of oxygen. The remedy for this deplorable condition

of things is largely in the power of the medical profession. If each doctor in this community would teach his patients the importance of pure air, there would be such a universal demand that those holding public office would be compelled to grant us better ventilation in public and private buildings, give us wider streets, more small gardens, less water gas, better sewage, cleaner streets, and less smoke and lower buildings, which latter would permit of the sun's rays shining to foundations of the buildings on at least one side of the street. The recent structures in the large cities in this country are monuments of ignorance of our people, that our descendants will censure us for in time not far off. Our streets will soon be but caverns such as the half-civilized man lived in centuries ago, mere fissures between great walls of stone and bricks; damp, sunless, and dirty, a sine qua non for disease germs. Less steam from the factories, locomotives, and engines should be demanded. These improvements would lead to a decrease in the mortality of children, crime, drunkenness and immorality and to a marked raising of our standard of mental power.

To-day it is a crying shame to our intelligent classes to analyze the air in our medical teaching institutions. Only a few years ago Dr. Kerlin made a series of important examinations of the hygienic conditions of the air in the lecture rooms of Medical Hall of the University of Pennsylvania, with the result of showing 17 per cent. of our index of impurities, or in other words the carbon dioxide raised from 4 parts in 10,000, to 17 parts in 10,000. While 6 parts in 10,000 represents the maximum of impurities in ordinarily well ventilated rooms, 7 in 10,000 is detected by the sense of smell.

In studying the etiology of disease, we must not permit ourselves to be persuaded that bacteriology has given us Le mot d' ènigme. Micro-organisms undoubtedly have the power when introduced into the circulation of healthy animals, of producing certain diseases, yet I feel convinced that in tuberculosis and many other germ diseases they in a large majority of instances, only change an already unhealthy tissue into one definitely and fatally morbid.

Normal tissues supplied with pure air have great power to resist germs taken into the body through either the digestive or respiratory tracts. This conclusion is reached from the fact that I found guinea pigs and rabbits yielded much more readily to inoculations by tubercle bacilli when confined in cages kept in the cellar under my city laboratory, than they did when kept in my animal house situated in the country and so arranged as to have a large volume of pure air circulating through it both day and night. To avoid tuberculosis we must recognize the predisposed habit of the individual and have him live in pure air and not breathe a deoxydized atmosphere, or air loaded with fibrous matter, or spiculated dust, or air impregnated with the products of combustion of coal, or the escape of water gas, or a high percentage of humidity, or air that has been robbed of the sun's rays. This last is not the least important. It not only prevents dampness but destroys poisons, such for instance as the woorara snake poison and bacteria. If such environments are not avoided a lower and lower vitality will creep on insiduously inch by inch until a pathological condition becomes recognizable both to the victim and his medical adviser. At this stage if not before, a nidus has been formed which is quite susceptible to the action of pathogenic minute life, and should the patient not be removed from the environment that predisposed him to the attack of the germs, his resisting powers will be still further reduced. It may however, be discovered early enough to not only prevent a greater degree of susceptibility but, by proper hygienic conditions, the tissues in many cases will return to that degree of health not suited to the lives of micro-organisms.

I do not mean to undertake to weigh the exact power of germs to break up the affinity of normal tissues when brought into contact with them in what we may call the natural way, to differentiate it from an artificial method. I do intend, however, to say that if we can maintain by the aid of pure air and proper physical exercise the integrity of function to a degree that renders the tissues almost impregnable to the attacks of micro-organisms, we must girdle ourselves with an armor of general good health if we wish to resist the attacks of minute life. The prevention of premature death, disabled physical and mental faculties, forms a far

more comprehensive question for the physician than does curative medicine, at the same time we must recognize that preventive and curative medicine are inseparable. While we are gathered together in convention, we all advocate hygienic measures, admitting them to be paramount to the more fruitless task of the so-called curative side of medicine; yet, I fear we are in preventive medicine too much like many of our Sunday Christians, who believe in the theory, yet forget its practical workings by the time the business houses of Monday morning open for trade. The physician of to-day who has been taught and believes in preventive medicine, too often empirically accepts disease as an existing condition and treats it accordingly until alleviated or cured. This stage reached he considers his work done until called in again, upon his patient becoming ill, probably with the accumulation of impure air and unhygienic habits. This may be pecuniarily profitable to the medical man, and might warrant the ignorant to attribute our laches regarding prevention to be entirely toward this selfish end. This, however, would be very unjust. We must account for the customary neglect of hygiene by the fact that both preventive and curative medicine were hidden in darkness for thousands of years and, therefore, the conservative, cautious and wise physician, with a full realization of his ignorance, only interfered with nature when appealed to act by the appeals of an acute sufferer, thence the habit. To-day, this should not be so; we do not regard disease as a visitation of the Almighty God, inscrutable in character. We sufficiently understand many of the predisposing and exciting causes to guide our fellow man through life free from the heretofore unknown poisons to a much more satisfactory degree than some of our forefathers, who believed themselves capable of curbing the wrath of God by the administration of their empirical remedies. This good fortune of ours, however, comes to us from the fact that, in all ages of medicine, our profession has been besprinkled with ambitious minds, who have labored to discover the causes of ill health, and methods to prevent disease, and now the time has arrived for us to come to a full realization of what has been demonstrated regarding man's power to prevent disease and adopt as our motto *venienti occurrite morbo*, hasten to meet the coming disease. Those factors essential for prevention often prove essential for cure, which fact is not recognized by many of our practitioners. For instance we frequently know of a physician who is called in to see a patient; he correctly diagnosticates the case as one of typhoid fever, and then simply applies his knowledge of the healing art. Oftentimes with as little success as if he had been administering to a person with symptoms of lead poisoning, who was at the same time continuing the use of water impregnated with the poison. He seldom interests himself to investigate and remove the source of poison but frequently orders the patient on a milk diet, thereby giving him every few hours the very vehicle that first carried the poison. I conceive it, however, to be our duty to at once investigate the water, food and air supplies, and thereby cut of all external source of further poisoning.
